RAYNAUD'S DISEASE AMONG MEN

EDGAR A. HINES JR., M.D.

AND

NORMAN A. CHRISTENSEN, M.D.

Fellow in Medicine, Mayo Foundation
ROCHESTER, MINN.

It has been assumed that Raynaud's disease occurs very rarely among men as compared with its occurrence among women. From both a diagnostic and a prognostic standpoint it is important that the physician be able to recognize Raynaud's disease both among men and among women and to distinguish it from other peripheral vascular diseases, especially from those in which there occurs a secondary form of Raynaud's phenomenon. The differential diagnosis of Raynaud's disease is more difficult among men than among women because of the relative infrequency of Raynaud's disease among men in comparison with the organic peripheral vascular diseases which may produce similar vasospastic phenomena in the extremities.

In reviewing 200 cases of thromboangiitis obliterans, Allen and Brown¹ found that Raynaud's phenomenon was the first symptom in 12 per cent and that it occurred at some time during the course of the disease in 30 per cent of all cases. Barker and one of us,² studying a group of 280 patients suffering from arteriosclerosis obliterans, found that Raynaud's phenomenon occurred in 10 per cent of the cases.

By Raynaud's phenomenon is meant the occurrence of intermittent episodes due to a functional vascular disturbance either primary or secondary, resulting in color changes of the extremities, principally the fingers and toes and less frequently the nose and ears, initiated by exposure to cold and less frequently by emotional or nervous strain and stress. When the condition is primary, it may be referred to as Raynaud's disease.

Pathologic changes in Raynaud's disease are minimal regardless of the duration. In many cases there are few or no organic vascular changes. In some of the cases of more severe Raynaud's disease of long duration one is able to demonstrate intimal thickening of the smaller arteries, and there may be small cutaneous trophic lesions with small regions of local necrosis and localized scleroderma.

Although Raynaud³ and later Hutchinson⁴ attempted to clarify the confused state of functional peripheral

vascular disturbances, it was not until Allen and Brown⁵ published their work in 1932 that the clinical syndrome of Raynaud's disease was clearly elucidated. After making a thorough review of the literature and of 150 cases at the Mayo Clinic, Allen and Brown presented a working basis for diagnosing this condition. The following is a summary of the criteria which should be observed in making a diagnosis of Raynaud's disease: (1) episodes of Raynaud's phenomenon *excited by cold or emotion*; (2) *bilaterality of Raynaud's phenomenon*; (3) *absence of gangrene*, or, if present, its limitation to minimal grades of cutaneous gangrene; (4) *absence of any primary disease which might be causal*, such as occlusive arterial disease, cervical rib or organic disease of the nervous system; (5) *symptoms of two years' or longer duration*.

In the 150 cases in which the diagnosis was Raynaud's disease and which were studied by Allen and Brown⁶ in 1932, 133 patients were female. The remaining 17 were male. Only 7 of the 17 cases in males met all the requirements of the criteria. In 10 cases the diagnosis of probable Raynaud's disease was made.

To our knowledge, a study of Raynaud's disease in a large group of men has not been made and no follow-up study for verification of the diagnosis has been made. It is our purpose in this paper to present such a study.

PRESENT STUDY

From January 1920 to December 1942 inclusive the diagnosis of Raynaud's disease, Raynaud's phenomenon or questionable Raynaud's disease was made for 847 patients coming to the Mayo Clinic. Because of the state of confusion in diagnosis prior to 1920, cases in which the diagnosis had been made previous to this time were omitted. Six hundred and forty-nine (77 per cent) of these patients were female. The remaining 198 (23 per cent) were male. The sex incidence of all patients entering the clinic during this period was about equal. It is of particular interest that the sex incidence for the group with a diagnosis of Raynaud's disease was likewise about equal from 1920 to 1924 inclusive. From 1925 on the incidence changed rather abruptly and has remained quite constant since, averaging approximately 21 per cent men and 79 per cent women. This change occurred at the time Brown, Allen, Barker, Horton and others of the Mayo Clinic became particularly interested in peripheral vascular diseases and about the time that Allen and Brown⁷ began considering a

more logical approach for making the diagnosis of Raynaud's disease.

Seventeen of the 198 cases in males were discarded from our study for various reasons. The remaining 181 cases were then carefully reviewed and, by means of the Allen-Brown criteria, were classified into three groups. Those that seemed to meet all the requirements of the criteria were grouped as "diagnosis adequate." Those that met the criteria except for some questionable reason, as insufficient duration, unilateral-

the remaining 5 per cent of the cases, but the site of involvement was not recorded.

As mentioned previously, classically many writers describe a three phase color-change in Raynaud's disease; the usual sequence being initial pallor, then cyanosis and finally rubor. In this group, of 100 cases detailed color changes were recorded in 63. The typical three phase color change occurred in only 22 per cent of this group. In many of the remaining 37 cases, Raynaud's phenomenon was mentioned but not described in detail. Probably in many of these there were multiphasic color changes but it was not possible to evaluate them. Pallor was the most frequent color change described; it occurred as the sole phase in 41 per cent of the 63 cases.

The excitant mechanism producing this phenomenon was given as "cold" in every case, and only in 9 cases was emotional or nervous strain mentioned as an additional excitant. Apparently the latter is a more important factor among women than among men.

Some writers have emphasized the frequency of associated functional or neurotic disturbances among patients having Raynaud's disease. In 29 of this group of 100 cases such disturbances were important enough to be included in the final diagnosis. The majority were either functional gastrointestinal disturbances or functional disturbances of the nervous system.

In 3 cases there was a familial history of Raynaud's phenomenon similar to that of the patient. In all 3 cases the mother was the one affected.

Of this group of 100 patients follow-up information was obtained on 69 during subsequent visits to the clinic or from follow-up letters. From this information an attempt was made to evaluate the therapeutic regimen followed by these patients. In general, treatment recommended to them varied and depended on the severity of the symptoms and the degree of incapacitation. Usually the patient was reassured that massive gangrene of the involved extremities followed by one or more amputations was not going to develop, as was feared by so many. The primary objects of treatment were reassurance and an attempt to remove the exciting factors from the patient or the patient from the exciting factors. Protection from cold and sudden changes of temperature was advised in all cases. Warm clothing, including woolen socks, gloves and ear muffs, was recommended. Changes of occupation or climate were suggested to some patients when they seemed advisable. Smoking was usually discouraged. When the patient's condition was incapacitating enough to warrant it, or when the foregoing conservative measures had failed to give proper relief or were not practicable, sympathectomy was recommended.

Of the 69 patients from this group who were followed up adequately, sympathectomy had been performed on only 2, and definite improvement of both was reported. This form of treatment was recommended to many other patients but was refused. In the remaining 67, for whom more conservative treatment was used, the following interesting results were obtained: Thirty-three per cent of the patients reported improvement so as to have little or no incapacitation at the time when they reported; 44 per cent reported that their status had remained practically the same or that they were reasonably well. The remaining 23 per cent of this group reported their symptom complex as being

ity of Raynaud's phenomenon, unrecorded or questionable peripheral pulsations or the possibility of the vasospasm being secondary to something else, were placed in the group designated as "diagnosis questionable" or probable Raynaud's disease. The third group consisted of cases in which, in our opinion, the diagnosis of Raynaud's disease should not have been made.

From the first two groups, in which the original diagnosis was thought either adequate or questionable, 100 cases were taken at random to make a general study of Raynaud's disease as it occurs among men. Cases and percentages will be used interchangeably because of the number chosen.

It was not surprising to find that in 73 per cent of this group the vasospastic symptoms had begun before the patient reached the age of 40 years (table 1) and that the greatest incidence of onset of symptoms occurred during the third and fourth decades. The youngest age of onset was given as 5 years and the oldest as 63 years. As many other writers have emphasized, Raynaud's disease is predominantly a disease of young adults.

In 91 per cent of this group, Raynaud's phenomenon had been present at least two years (table 1). Fifty-nine per cent of the patients had had their vasospastic symptoms for six years or more. Eleven per cent of them had had symptoms for twenty-one years or longer. The longest duration was given as fifty years.

Vasospastic changes occurred most frequently in the fingers. In 61 per cent of this group of patients the fingers, or less frequently the fingers and hands, alone were involved. Raynaud's phenomenon was recorded as being unilateral in 16 per cent of the cases. None of these 100 patients had vasospastic changes involving the feet alone, but in 36 per cent the hands and feet were both affected. In 3 instances color changes also occurred in the external ears, and in a single case the nose was involved. Vasospastic changes occurred in

worse at the time of the follow-up than at the time of their last visit to the clinic. In summary, 77 per cent of these patients have enjoyed reasonably good health or at least have not become any worse following the conservative measures as outlined.

From a therapeutic standpoint an attempt was made to evaluate the effect of tobacco on these patients. Of the group of 69 patients 66 per cent were users of tobacco. Some patients improved considerably after reducing or stopping the use of tobacco. On the other hand, about as many improved while they continued smoking and in some instances improvement occurred even when the use of tobacco had been increased. A few patients who had continued smoking one to two packages of cigarets daily were among those reporting improvement of their Raynaud's disease. On the other hand, some who continued to smoke heavily became worse. The majority of the patients in all groups, whether nonsmokers, mild smokers or heavy smokers, followed a rather similar course. Consequently it is impossible from our studies to say that tobacco is or is not harmful to these patients.

The remaining portion of this study pertains to a follow-up study for the verification of the diagnosis of Raynaud's disease among men.

Of the total of 181 male patients who had had a diagnosis of Raynaud's disease on the original visit, follow-up information was obtained on 100. This information was secured either from follow-up letters or from records of subsequent visits. Again the number of cases and percentage can be used interchangeably.

The 100 cases were first divided into two main subgroups depending on the original diagnosis. In 58 cases the original diagnosis had been Raynaud's disease (no question) and in the remaining 42 the diagnosis had been questionable Raynaud's disease. The adequacy of the original diagnosis in each case was then

"diagnosis adequate." Follow-up information obtained two to many years after the original diagnosis revealed that 26 of the 30 (87 per cent) still met the requirements for an adequate diagnosis. The diagnosis in 4 cases now seems inadequate. Raynaud's phenomenon is now absent in 2 of the 4, and in another evidence

of extensive scleroderma has since developed. One patient had died.

The adequacy of the original diagnosis seemed questionable in 21 of the 58 cases. Sixteen of the 21 patients had had Raynaud's phenomenon for less than two years or the duration was not recorded. In the other 5 Raynaud's phenomenon was recorded as being unilateral.

Follow-up studies of this group of 21 cases revealed that in 16 (76 per cent) the diagnosis now seems adequate. In 2 cases Raynaud's phenomenon is still unilateral and therefore the diagnosis still remains questionable. The vasospastic changes have ceased to occur in 2 other cases. The remaining patient has died.

Seven of the 58 cases in which an original diagnosis of Raynaud's disease had been made failed to meet the Allen-Brown criteria and so were classified as "diagnosis inadequate or incorrect." Follow-up studies verified this impression. In 6 of these cases there is now some other disease with secondary Raynaud's phenomenon. In 1 case Raynaud's phenomenon no longer occurs.

The second large subgroup consists of 42 cases in which the original diagnosis had been questionable Raynaud's disease or probable Raynaud's disease (table 3). Again using the Allen-Brown criteria as a working basis, this group of cases was reviewed in the same manner as was the first group so that the adequacy of the original and subsequent diagnosis might be evaluated. In 4 of these cases all the requirements of the criteria were fulfilled. In our opinion a diagnosis of Raynaud's disease (no question) should have been made on the original visit. Follow-up studies verified this impression, as the diagnosis of unquestionable Raynaud's disease still seems adequate after two to many years in all 4 cases.

evaluated, using the Allen-Brown criteria as a working basis. Finally, the follow-up information in each case was likewise analyzed and the diagnosis reevaluated using the same criteria.

Thirty of the 58 cases (table 2) in which the original diagnosis had been Raynaud's disease (no question) seemed to meet all the requirements for a certain diagnosis of Raynaud's disease. These were grouped as

In our opinion, in 5 of this group of 42 cases the original diagnosis failed to meet the criteria for diagnosis of Raynaud's disease or of questionable Raynaud's disease and so we classified it as incorrect. Follow-up studies verified our impression. We agreed with the original diagnosis of questionable Raynaud's disease in 33 of the 42 cases. Thirteen of these 33 patients had had Raynaud's phenomenon less than two years or the duration was not recorded. The peripheral arterial pulsations were questionable or unrecorded in 8 cases. The vasospastic phenomenon was possibly secondary in 8 cases and it was unilateral in 4 other cases.

Follow-up studies of this group of 33 cases now reveal that 13 cases (39 per cent) fulfil the criteria and that a diagnosis of Raynaud's disease can now be made. The adequacy still remains questionable in 7. Progressing acrosclerosis is present in 5 other cases, while in 3 there is now evidence of thromboangiitis obliterans. The vasospastic changes have ceased to occur in 3 cases. Two patients have died.

COMMENT

One of the purposes of this study has been to gain a fuller knowledge of Raynaud's disease affecting men. In the past it has been difficult to make a diagnosis of Raynaud's disease among men without viewing that diagnosis with suspicion and feeling that some other pathologic entity, such as thromboangiitis obliterans, arteriosclerosis obliterans or scleroderma, which would explain the Raynaud phenomenon, would eventually develop. Our follow-up studies seem to prove that by following the criteria of Allen and Brown a diagnosis of Raynaud's disease can be made with confidence that some other form of peripheral vascular disease will not become apparent later. The only question regarding the criteria arising at this time is whether the phenomenon must be always bilateral. In 16 per cent of the 76 selected cases of questionable Raynaud's disease, Raynaud's phenomenon continued to be unilateral after two or more years without the development of any possible secondary cause for the phenomenon. Another interesting question that has arisen in our minds is how to interpret and incorporate the 7 cases in which Raynaud's phenomenon was occurring at the time of a previous visit but has since ceased. First of all we wonder if the patients had Raynaud's disease. Secondly, if they did, has the disease been cured or is the patient in a state of remission? Only time and further study can answer these questions.

The early establishment of a correct diagnosis of Raynaud's disease is of considerable importance to the patient. Raynaud's disease is usually a more benign disease than the more serious diseases which have Raynaud's phenomenon as a secondary manifestation, such as thromboangiitis obliterans, arteriosclerosis obliterans and scleroderma. If a diagnosis of Raynaud's disease can be made, the physician can give the patient assurance of a better prognosis than in most of the other conditions associated with secondary Raynaud's phenomenon and adequate treatment for Raynaud's disease can be instituted at an earlier date.

The treatment of Raynaud's disease depends on the degree of incapacitation. A conservative program of treatment is worth while when the disease is not too

incapacitating. These measures are not curative but merely prophylactic. The patient is advised to avoid exposure to cold or changes of temperature. This may mean advising him to change his occupation or to move to a warmer climate. Protective clothing alone helps in many cases of mild Raynaud's disease. Although in the majority of instances tobacco apparently has no relationship either to the symptoms or to the course of the disease, a few patients are definitely benefited by abstinence. The new patient, if a user of tobacco, should at least give himself a fair trial of abstinence to determine if he is one who might be benefited.

Sympathectomy was done in 2 cases and recommended in others. Prompt relief followed in both cases so that there was much less incapacitation than before operation. Sympathectomy has been done with relief of vasospasm on many more women suffering from Raynaud's disease. Whenever the patient is considerably incapacitated and is unable to get relief from or follow the more conservative measures, sympathectomy should be considered.

SUMMARY

Of the 847 patients diagnosed as having Raynaud's disease or questionable Raynaud's disease at the Mayo Clinic between the years 1920 and 1942 inclusive, 198 were men. Seventeen of the latter group were discarded from our study. About 1925 the incidence of men to women changed definitely from an incidence of 50 per cent men and 50 per cent women to an incidence which has remained constant, 21 per cent men and 79 per cent women. Allen and Brown's criteria formulated about that time is a possible reason for this change.

A study of the nature and course of the disease was made on an unselected group of 100 of the 181 male patients. Follow-up studies were done on 69 of these patients. Sympathectomy had been performed on 2 of the 69, with improvement in both. In 33 per cent of the 67 cases in which more conservative treatment was used the condition had improved, in 44 per cent it was unchanged and in 23 per cent it was worse. The data on the effect of tobacco on Raynaud's disease are inconclusive.

An evaluation of the original diagnosis and a follow-up study were carried out in 100 of the 181 cases. Using the criteria of Allen and Brown,⁵ the diagnosis on the original visit seemed adequate in 34, questionable in 54 and incorrect in 12. Of the 34 cases in which the diagnosis seemed adequate on the original examination, the follow-up study revealed that in 30 (88 per cent) the diagnosis was still adequate and evidence of any other disease which might have produced the symptoms secondarily had not developed. Of the 88 cases in which an original diagnosis of either Raynaud's disease or questionable Raynaud's disease had been made, the diagnosis of Raynaud's disease should be certified on the follow-up study in 59 (67 per cent). These data indicate that, if care is given to the use of adequate criteria for the diagnosis of Raynaud's disease, this diagnosis can be made and verified on a follow-up study in a much greater number of cases than has previously been considered probable by most students of peripheral vascular diseases.

ETIOLOGY OF THROMBOANGIITIS
OBLITERANSSAMUEL SILBERT, M.D.
NEW YORK

The etiology of thromboangiitis obliterans has been obscure ever since the first differentiation by Buerger between this condition and other forms of peripheral vascular disease. Impressed by the inflammatory type of lesions seen in the blood vessels, Buerger¹ regarded the disease as an infection, but all the clinical evidence indicates that this conception is incorrect. Goodman² agrees that thromboangiitis obliterans is an infectious disease and holds that an attenuated virus of typhus is responsible for it.³ Kaunitz⁴ suggests that chronic ergot poisoning from eating infected rye foods causes the disease, and recently Thompson⁵ has claimed that fungous infection (dermatophytosis) is the causative agent. The occurrence of the disease in smokers has been commented on by several writers. Erb⁶ in 1904 stated that smoking was an important contributing cause of this condition. Lilienthal⁷ noted this relationship in 1914, and Willy Meyer⁸ in 1920 expressed the conviction that thromboangiitis obliterans was due to the use of tobacco.

Thromboangiitis obliterans has interested me profoundly for twenty years, and during this time it has been my unusual opportunity to study in clinic and private practice over 1,400 cases of this disease. Hundreds of these cases have been followed for many years. Certain observations have emerged from this experience which have a bearing on the question of etiology.

The first of these is the incidence of the disease in the two sexes. In this series only 12 cases of thromboangiitis obliterans have been seen in women, an incidence of less than 1 per cent, while over 99 per cent have occurred in men. The infrequency of the disease in the female has been noted by other observers.⁹ There is no known infection which affects almost exclusively one sex, and nothing known about the activities of micro-organisms or viruses warrants the belief that the female sex enjoys any special immunity. On this basis alone, theories that thromboangiitis obliterans are due to any form of infection fail to be convincing.

The second observation is that without exception all men and women with thromboangiitis obliterans have been smokers of tobacco. The statement appears frequently in medical literature that instances of this dis-

ease have been seen in nonsmokers. This is contrary to my experience. It is not difficult to explain this difference of opinion. It is easy to confuse peripheral vascular disease due to thromboangiitis obliterans with that due to presenile arteriosclerosis, an entirely different disease. This is particularly true in the age group between 40 and 55. In both conditions the symptoms, such as intermittent claudication, rest pain, coldness and numbness of the extremities, will be present. In both conditions the local signs, the absence of pulsations, the diminished oscillometric readings, the reduced temperature of the feet, the presence of ulcers or gangrene will be the same. A clinical differentiation rests on the recognition that when an individual shows signs of arteriosclerosis in other parts of his body the disease process in his legs is due to the same cause and is not due to thromboangiitis obliterans. Each patient should be carefully scanned from head to foot to elicit signs of arteriosclerosis. In table 1 there are listed the signs regarded as particularly significant. It should be emphasized that no one sign is looked on as decisive

TABLE 1.—Criteria for Differentiation Between Thromboangiitis Obliterans and Arteriosclerosis in Patients Between 40 and 50 Years of Age

Thromboangiitis obliterans	Arteriosclerosis
Appears younger than his age	Appears older than his age
Hair normally pigmented	Hair usually gray
No arcus senilis	Arcus senilis frequently present
Retinal arteries normal	Retinal arteries usually sclerotic
Blood pressure usually low	Blood pressure often high
Radial and temporal vessels soft	Radial and temporal vessels thickened and hard
Upper extremities frequently involved	Upper extremities seldom involved
Femoral arteries frequently closed	Femoral arteries seldom closed
No calcification of vessels on x-ray examination	Calcification of vessels on x-ray examination frequently seen
Blood volume usually diminished	Blood volume usually normal
Symptoms of coronary artery sclerosis rare	Symptoms of coronary artery sclerosis frequent
Aorta appears normal on x-ray examination	Aorta sometimes appears elongated on x-ray examination
Albuminuria rare	Albuminuria not uncommon
History of migrating phlebitis frequent	History of migrating phlebitis rare

for differentiation. Rather each disease has a general pattern which usually makes distinction possible.

Care must also be used to exclude instances of peripheral arterial disease due to syphilis, embolism, trauma, polycythemia, poisoning from ergot or arteritis due to influenza, typhus or rheumatism. Thromboangiitis obliterans is a diagnosis made by exclusion, and there are no pathognomonic symptoms or signs by which it can be absolutely identified. Critical scrutiny of every case is necessary to establish the true nature of the disease. Those who carelessly report all cases of occlusive arterial disease in young people as thromboangiitis obliterans confuse medical literature and obscure the simple facts about this disease which are so clear and important.

The third point that is learned from the clinical experience with thromboangiitis obliterans is that the disease is almost uniformly progressive in individuals who continue smoking. In such patients early symptoms are soon followed by ulcers of the toes, gangrene and amputations of the extremity. The disease progresses from extremity to extremity, frequently causing the loss of one or both legs and occasionally one or both arms as well. In the group of 1,400 patients that

I have studied 174 have lost one leg, 100 both legs, 1 one leg and both arms, 2 both legs and one arm and 2 both legs and both arms.

The final fact that is evident from a study of patients with thromboangiitis obliterans is that the disease is immediately and completely arrested in individuals who permanently discontinue smoking. The disease process may be compared to a house on fire; with cessation of smoking the fire is extinguished. Damage has been done by the fire which must be repaired, but the house is no longer burning down. In support of this statement, the case histories of 100 patients with thromboangiitis obliterans, followed personally from ten to twenty years, is summarized in table 2. No patient is included whose age of onset of symptoms was over 45, who had a blood pressure of over 160 when trouble in the legs first developed, who showed calcification of the blood vessels on x-ray examination, whose Wasser-

mann test was positive at any time or who suffered from rheumatic heart disease. All patients included had thromboses of major peripheral arteries in one or more extremities. This table includes all patients with thromboangiitis obliterans who have been followed over ten years and who have completely given up the use of tobacco. Eighty-three of these patients had no amputation when first seen, 15 already had one leg amputated and 2 had both legs off. It will be noted that in nearly all of the patients listed the onset of the peripheral vascular disease was between the ages of 20 and 40, the characteristic age of onset for patients with thromboangiitis obliterans. All of these patients were smokers; all of them stopped smoking throughout this period of observation. With few exceptions, all are well and working at various occupations, requiring no treatment. Ten illustrative cases will be cited in detail, but in one respect all of them are alike. In no instance

TABLE 2.—Patients with Thromboangiitis Obliterans Followed Ten to Twenty Years

Case	Patient	Age of Onset	Year of First Examination	Duration of Illness When First Seen	Symptoms *	Degree of Circulatory Impairment †	Local Lesions	Year of Last Examination	No. of Years Observed	Work- ing	Occupation
No Amputations											
1	M. S.	37	1923	2 yrs.	Pain	2+	Ulcer of toe	1943	20	Yes	Gelatin mixer
2	H. H.	38	1924	1 yr.	Pain	3+	Ulcer of toe	1944	20	Yes	Barber
3	I. K.	30	1924	3 yrs.	Intermittent claudication	2+	Ulcer of toe	1943	19	Yes	Cutter
4	H. L.	26	1924	5 yrs.	Pain	2+	Ulcer of toe	1943	19	Yes	Cutter or presser
5	S. K.	40	1925	6 yrs.	Pain	2+	Ulcer of toe	1943	18	Yes	Operator
6	S. J.	25	1925	1 yr.	Intermittent claudication	3+	Ulcer of toe	1943	18	Yes	Truck driver
7	J. M.	23	1926	3 yrs.	Pain, coldness	3+	None	1944	15	Yes	Garage mechanic
8	E. R.	24	1925	½ yr.	Pain	3+	None	1943	18	Yes	Insurance agent
9	J. L.	33	1926	1½ yrs.	I. C., rest pain	2+	None	1944	18	Yes	Operator
10	M. S.	37	1925	10 yrs.	Intermittent claudication	3+	None	1942	17	No	Brick layer
11	G. A.	28	1926	4 yrs.	Pain	2+	None	1943	17	Yes	Chauffeur
12	B. M.	44	1926	2 yrs.	I. C., (2 blocks), coldness, rest pain	3+	None	1943	17	Yes	Grocery clerk
13	N. R.	27	1927	14 yrs.	I. C. (3-4 blocks)	2+	None	1943	16	Yes	Hairdresser
14	I. K.	33	1927	2 yrs.	I. C. (¼ block), coldness	2+	None	1943	16	Yes	Musician
15	J. W.	31	1928	3 yrs.	I. C. (2 blocks), numbness	3+	None	1944	16	Yes	Salesman
16	J. S.	34	1928	2 yrs.	I. C. (1 block), coldness	3+	Small ulcer, left foot	1944	16	Yes	Storekeeper
17	A. G.	32	1928	10 yrs.	I. C. (2 blocks)	2+	None	1944	16	No	Butcher
18	J. W.	33	1927	2 yrs.	I. C., severe rest pain	3+	None	1944	16	Yes	Lumber business
19	V. N.	35	1927	1 yr.	I. C. (3 blocks), coldness	2+	None	1943	16	Yes	Market inspector
20	J. B.	39	1927	2 yrs.	I. C., rest pain, numbness	3+	None	1942	15	Yes	Tailor
21	H. M.	40	1926	1 yr.	Intermittent claudication	3+	None	1941	15	Yes	Storekeeper
22	J. R.	43	1926	3 yrs.	Intermittent claudication	3+	None	1941	15	Yes	Merchant
23	S. S.	40	1929	3 yrs.	Coldness, pain	2+	Ulcer, right big toe	1944	15	Yes	Finisher
24	L. W.	30	1929	5 yrs.	I. C. (3 blocks), rest pain	2+	Ulcer, right big toe	1944	15	Yes	Embroiderer
25	I. A.	40	1929	1 yr.	I. C. (few steps), coldness	2+	None	1941	14	Yes	Waiter
26	J. F.	25	1928	1 yr.	I. C., rest pain	1+	Ulcer, right 2d toe	1942	14	Yes	Clerk
27	S. N.	43	1926	1 yr.	I. C. (1 block), rest pain	3+	Ulcer, outer side left big toe	1940	14	Yes	Merchant
28	R. M.	31	1930	3 yrs.	Intermittent claudication	3+	Extensive ulcer, right foot, unhealed wound	1944	14	Yes	Farmer
29	D. B.	38	1929	½ yr.	I. C. (10 blocks), pain	2+	None	1943	14	Yes	Walter
30	J. E.	35	1929	1 yr.	I. C., rest pain	3+	Ulcer (gangrenous), right 4th toe	1943	11	Yes	Milliner
31	H. L.	35	1930	¼ yr.	Pain	1+	Ulcer, left big toe, right 2d toe	1944	14	Yes	Bus driver
32	L. F.	42	1929	¾ yr.	I. C. (10 blocks)	1+	None	1943	14	Yes	Lawyer
33	L. A.	30	1930	7 yrs.	Pain	1+	Ulcer	1944	14	Yes	Operator
34	D. G.	32	1930	2 yrs.	I. C. (5 blocks), numbness	2+	None	1944	14	Yes	Shoe salesman
35	M. D.	37	1929	1½ yrs.	I. C., rest pain	2+	Superficial ulcer, right 4th toe	1943	14	Yes	Plumber
36	A. H.	33	1930	2 yrs.	I. C., rest pain	2+	Ulcer, right 5th toe	1944	14	Yes	Collector
37	B. B.	29	1930	6 yrs.	Severe rest pain	3+	Ulcers (multiple) left foot	1943	13	Yes	Clerk
38	M. K.	38	1930	2 yrs.	Pain	3+	None	1941	13	Yes	Painter
39	H. R.	26	1930	3 yrs.	Pain	2+	None	1943	13	Yes	Foreman, shoe factory
40	S. P.	38	1930	4 yrs.	I. C. (4 blocks), rest pain	3+	Gangrene, left 2d toe; ulcers (multiple) left foot	1943	13	Yes	Storekeeper
41	D. L.	37	1928	½ yr.	Coldness, numbness, phlebitis	1+	None	1941	13	Yes	Letter carrier
42	B. M.	43	1928	4 yrs.	I. C. (1½ blocks)	3+	None	1941	13	Yes	Shoe machine operator
43	M. K.	41	1929	1 yr.	I. C. (3 blocks)	1+	None	1942	13	Yes	Doctor
44	M. K.	20	1931	2 yrs.	Rest pain, pain on walking	2+	Ulcer, left 5th toe	1944	13	Yes	Bus driver
45	R. L.	40	1930	1 yr.	I. C., numbness	2+	None	1943	13	Yes	Physical instructor
46	J. A.	44	1931	¼ yr.	I. C. (2 blocks), pain	2+	None	1944	13	Yes	Cutter
47	R. K.	23	1931	3 yrs.	Rest pain, coldness	2+	Ulcer	1944	13	Yes	Operator
48	J. R.	37	1931	3 yrs.	Pain, coldness	2+	Ulcer of foot	1944	13	Yes	Operator
49	H. K.	28	1930	1 yr.	I. C. (3 blocks)	3+	None	1943	13	Yes	Painter
50	G. S.	32	1931	5 wks.	I. C. (1 block)	3+	None	1944	13	Yes	Businessman
51	H. G.	23	1930	1 yr.	Intermittent claudication	1+	Healed ulcer	1942	13	Yes	Clerk
52	D. S.	26	1931	1 yr.	I. C., rest pain, coldness	2+	None; discoloration 2d toe	1943	12	Yes	Salesman
53	P. D.	51	1930	1 yr.	I. C. (1 block), severe rest pain	2+	Gangrenous ulcers on both big toes and right 2d toe	1942	12	Yes	Stationary business
54	J. W.	22	1930	5 yrs.	I. C. (5 blocks), coldness, rest pain	2+	Gangrene, 2d and 4th left toes; ulcers, left 4th toe	1942	12	Yes	Furrier
55	P. S.	26	1929	2 yrs.	I. C., rest pain	2+	None	1941	12	Yes	Operator
56	A. W.	21	1929	9 yrs.	I. C. (5 blocks), coldness	2+	None	1941	12	Yes	Furrier
57	I. G.	21	1928	12 yrs.	I. C. (2 blocks)	3+	None	1940	12	Yes	Furrier
58	C. F.	40	1932	8 yrs.	I. C. (1 block), severe rest pain	2+	Gangrene, 4 inner toes right foot; gangrene, both thumbs, right index finger	1944	12	Yes	Newspaper foreman
59	J. T.	22	1932	½ yr.	Pain	2+	None	1944	12	Yes	Postoffice clerk

TABLE 2—Patients with Thromboangiitis Obliterans Followed Ten to Twenty Years—Continued

Case	Patient	Age	Year of Onset	Year of First Examination	Duration of Illness When First Seen	Symptoms *	Degree of Circulatory Impairment †	Local Lesions	Year of Last Examination	No. of Years Observed	Working	Occupation

* I C, intermittent claudication

† Explanation of degree of circulatory impairment 4+, femoral, popliteal, anterior tibial and posterior tibial arteries closed, 3+, femoral open, popliteal, anterior tibial and posterior tibial arteries closed, 2+, femoral and popliteal open, anterior tibial and posterior tibial arteries closed, 1+, femoral, popliteal and one foot pulse open, one foot pulse closed

has there been any progression of the vascular disease since the use of tobacco was stopped, and not 1 patient in this group required an amputation. What is true of this 100 cases is also true of several hundred other patients with thromboangiitis obliterans followed less than ten years.

No measures of any kind to combat infection were used in this group of patients. None were prohibited from eating rye bread or using rye whisky, nor were there any other restrictions of diet. A few of them showed signs of epidermophytosis between the toes. Thus, if any of the foregoing factors were responsible for the disease, progression should have taken place. Surely, it cannot be a coincidence that in not 1 of the 100 cases studied was any progression observed. This fact should be contrasted to the uniform progression of the disease in patients who continue smoking.

The evidence is convincing that the use of tobacco is the sole factor constantly associated with the occurrence

and the progression of thromboangiitis obliterans. However, it is also clear that millions of men and women smoke incessantly without developing this disease. Why is it that a practice which so many indulge with impunity is so harmful to a few? Certainly a constitutional factor, a special sensitivity of the blood vessels to the effects of tobacco, must also be present. Only those who have such a constitutional factor will develop thromboangiitis obliterans from smoking.

The rarity of thromboangiitis obliterans in the female sex indicates that women either have a biologic protection against the effects of tobacco or fail to inherit the constitutional factor necessary to make them susceptible. That a biologic protection is present appears unlikely. The 12 women in my series who presented typical instances of thromboangiitis obliterans differed in no apparent way from other members of the female sex. Whatever biologic protection other women have against the effects of tobacco should also have been present in

these 12 individuals. It is tempting to regard thromboangiitis obliterans as a sex linked disease, similar to hemophilia and color blindness. In such conditions the disease is transmitted through the female as a recessive trait and appears only in the male. Under the rare conditions in which the father has the disease and the mother carries it as a recessive trait, the daughter may show the condition. Unfortunately, in no instance have I been able to demonstrate such an occurrence in the parents of the female patients with thromboangiitis obliterans. For the present it must remain only a surmise that the constitutional factor which is responsible for thromboangiitis obliterans is inherited along sex linked lines.

TEN CASE HISTORIES

CASE 1.—J. W., an upholsterer, was first seen in December 1929, at which time he was 26 years old. He gave a history of intermittent claudication in the left leg for five years. Four months previously he had developed gangrene of the left second and fourth toes. He began to smoke at the age of 15, averaging about twenty cigarettes a day. The patient was well nourished. The general physical examination was negative. The circulation in the upper extremities was normal. Both femoral and both popliteal pulsations were present. The right anterior tibial and dorsalis pedis pulses were present. The right posterior tibial pulse was absent. There was no pulsation in the left foot. The left foot showed pronounced rubor and was very cold. There was gangrene of the left second and fourth toes. The oscillometer readings were right calf 4, right ankle $1\frac{1}{2}$, left calf $\frac{1}{2}$, left ankle 0. He stopped smoking and was treated with intravenous injections of 5 per cent saline solution. The gangrenous lesions separated, leaving ulcers on the toes. By May 1930 the ulcers were healed and he was able to walk five blocks without stopping. In November 1930 he could walk ten blocks and he returned to work. At that time the pulsations in the foot were the same as previously noted. The oscillometer readings were greatly improved. They were right calf $9\frac{1}{2}$, right ankle 4, left calf $3\frac{1}{2}$, left ankle faint. Treatment was discontinued at this time. The patient has remained in good condition and has been working regularly during the past twelve years. He has had no recurrence of circulatory trouble in the legs. He was last examined in August 1942. At this time the right anterior tibial and dorsalis pedis pulsations were present as before. No other pulse was present in either foot. The oscillometer readings were right ankle $2\frac{1}{2}$, left ankle $\frac{1}{2}$.

CASE 2.—D. P., a merchant, was first seen in April 1930, at which time he was 32 years old. He gave a history of migrating phlebitis of both legs for one year. For three months he had ulcers on both great toes and the right second toe. He began to smoke at the age of 15, smoking about twenty cigarettes a day. He was well nourished. The general physical examination was negative. The circulation in the upper extremities was normal. Both femoral and both popliteal pulses were present. All normal pulsations were absent in both feet. On the outer side of the left ankle there was a peroneal pulsation. There were two gangrenous ulcers on the left great toe, each of which measured 2 cm. in diameter. There was a gangrenous ulcer of the same size on the right great toe and a smaller ulcer on the right second toe. The oscillometer readings were right calf $4\frac{1}{2}$, right ankle $\frac{1}{4}$, left calf $5\frac{1}{2}$, left ankle $2\frac{1}{2}$. The patient was treated with cessation of smoking, bed rest and injections of 5 per cent sodium chloride solution. His condition improved steadily. By January 1931 all ulcers were completely healed, he was able to walk three blocks without discomfort and he had returned to work. Saline injections were continued until October 1932. At this time good pulsations were present on the outer side of both ankles. The oscillometer readings were right ankle $1\frac{1}{2}$, left ankle $2\frac{1}{2}$. Treatment was discontinued at that time because the circulation was regarded as satisfactory and the patient had no symptoms.

He has received no treatment since then. He has continued at his work without interruption for the past ten years. He was last examined in August 1942. At this time the left posterior tibial and left dorsalis pedis pulses had returned. Both peroneal pulsations were present as before. The oscillometer readings were right ankle $1\frac{1}{2}$, left ankle 3.

CASE 3.—E. R., an insurance agent, was first seen in the outpatient department of the Mount Sinai Hospital in November 1924, at which time he was 23 years old. He gave a history of intermittent claudication in both legs for three months. For ten weeks he had had severe pain in the right foot, which had made it impossible for him to work. There was no ulceration. He was well nourished. The general physical examination was negative. The left radial and right ulnar pulses were absent. The right radial and the left ulnar pulses were present. Both femoral and the left popliteal arteries were open. The right popliteal artery was closed. The left posterior tibial pulse was present. The left anterior tibial and dorsalis pedis were absent. There was no pulse in the right foot. He stopped smoking and received injections of hypertonic saline solution, at first three times a week and later less frequently. Treatment was continued for about a year. He has had no treatment since the end of 1925. He has remained in excellent condition and has had no further trouble with his feet. He is able to do his work as a life insurance agent, which requires him to climb stairs a good deal during the day. He was last examined in May 1943. He reported that he walks a mile easily and is still working as an insurance salesman. Examination showed the right radial pulse open; the right ulnar pulse was closed; the left radial pulse was closed; the left ulnar pulse was open; good posterior tibial pulses were present in both legs. The oscillometer readings were right calf $3\frac{1}{2}$, right ankle $1\frac{1}{4}$, left calf 5, left ankle $2\frac{1}{2}$.

CASE 4.—J. M., a garage mechanic, was first seen in February 1926, at which time he was 26 years old. He gave a history of migrating phlebitis in both legs for two years. For eight months there had been severe pain in the left ankle, and he walked with a decided limp. He smoked twelve cigarettes a day. He was well nourished. The general physical examination was negative. The circulation in the left upper extremity was normal. The right radial was closed, the right ulnar was open. Both femoral and the right popliteal arteries were open. The left popliteal artery was closed. The right posterior tibial pulse was good. There was no other pulse in the right foot and no pulse in the left foot. The left foot was extremely cold and deeply cyanotic. There were no ulcers. The oscillometer readings were right calf 8, right ankle 5, left calf $1\frac{1}{2}$, left ankle very faint. He stopped smoking and was treated with intravenous injections of hypertonic salt solution from February 1926 to February 1928. The symptoms cleared up completely and he returned to work and has continued to work ever since. There has been no recurrence of trouble with his legs. He was last examined in January 1944. At this examination all pulses were present in the right foot. There was a small left posterior tibial pulse. There was no other pulse in the left foot. Both feet were warm and normal in color. The oscillometer readings were right ankle 4, left ankle $1\frac{1}{4}$.

CASE 5.—J. S., a painter, was first seen in October 1928, at which time he was 36 years old. He gave a history of pain and coldness in the left leg for two years. He had intermittent claudication after walking one block. He smoked ten cigarettes a day. He was well nourished. The general physical examination was negative. The left ulnar pulse was absent. All other pulses were present in the upper extremities. Both femoral and the right popliteal arteries were open. The left popliteal artery was closed. There was no pulse in either foot. The left foot presented typical glossy redness in the dependent position. The oscillometer readings were right calf $1\frac{1}{2}$, right ankle very faint, left calf very faint, left ankle zero. He stopped smoking and was treated with injections of hypertonic salt solution twice a week until October 1930. At this time he was able to walk ten blocks easily without pain. Both

feet were warm. He returned to his work as a painter and has been working regularly since then. He has been examined periodically. He was last examined in April 1943. At this time he reported that he had no symptoms in his legs. Both popliteal arteries were now open but there was still no pulse in either foot. However, the oscillometer readings had shown considerable improvement and were now right calf 4, right ankle $1\frac{1}{2}$, left calf 3, left ankle 1.

CASE 6.—M. G. was first seen in January 1922, at which time he was 28 years old. He had severe pain in his left foot for six weeks and during this time he had an extensive ulcer on the left first toe. He smoked fifteen cigarettes daily and continued to do so. In spite of conservative treatment gangrene of the left lower extremity developed and a left mid-thigh amputation was done at the Mount Sinai Hospital in 1924. The stump healed by primary union. At this time he stopped smoking. He was well nourished. The general physical examination was negative. The left lower extremity was amputated through the midthigh. The right femoral and popliteal arteries were open. The right posterior tibial pulse was good. The right anterior tibial and dorsalis pedis pulses were absent. There was a good pulse on the outer side of the right ankle. The oscillometer reading was right ankle 5. The patient was told to refrain from smoking. He has been given no treatment and has been examined every year since 1924. On his last examination in June 1944 he was in excellent general health. The right posterior tibial and peroneal pulsations were present as they had been throughout the twenty years of observation. The oscillometer reading was right ankle 5. There was no evidence of any progression in the patient's condition.

CASE 7.—J. E., a millinery operator, was first seen in June 1929, when he was 36 years old. He gave a history of severe pain in the right foot, and for four weeks gangrene had been present on the right first toe. He smoked fifteen cigarettes a day. He was well nourished. The general physical examination was negative. The circulation in the upper extremities was normal. Both femoral and the left popliteal arteries were open. The right popliteal artery was closed. All pulsations were present in the left foot. There was no pulsation in the right foot. There was an area of gangrene 1 cm. in diameter on the base of the right great toe. There was a gangrenous ulcer 2 cm. in diameter on the outer side of the right fourth toe. The oscillometer readings were right calf very faint, right ankle 0, left calf 6, left ankle 3. The patient stopped smoking. He was treated with intravenous injections of hypertonic salt solution until early in 1932. His condition improved strikingly. His foot healed and he was able to walk twenty blocks without stopping. He has continued to be examined periodically, the last time in June 1943. At this time all pulses were present in the left foot. There was no pulse in the right foot. The oscillometer readings were right calf 2, right ankle $\frac{1}{2}$, left ankle $3\frac{1}{2}$. He had remained in excellent condition throughout the eleven years since treatment was stopped.

CASE 8.—H. K., a painter, was first seen in the outpatient department of the Mount Sinai Hospital in July 1930, at which time he was 38 years old. He gave a history of intermittent claudication in the left leg for eight months. He was unable to walk more than three blocks without stopping. There was no history of migrating phlebitis or ulcerations of the toes. He smoked about twenty cigarettes a day. He was well nourished. The general physical examination was negative. All pulsations were present at both wrists. The right femoral and popliteal arteries were open; the left femoral and popliteal arteries were closed. All normal pulsations were present in the right foot. There was no pulsation in the left foot. The oscillometer readings were right calf $3\frac{1}{2}$, right ankle $1\frac{1}{2}$, left calf $\frac{1}{4}$, left ankle 0. He stopped smoking and was treated for one year with saline injections. He has had no treatment since then. When last examined in May 1943 he was in good condition, working as a painter, and not smoking. He was able to walk fifteen blocks without stopping. All pulses could be felt in both feet. The oscillometer readings were right calf 10, right ankle $3\frac{1}{4}$, left calf $2\frac{1}{2}$, left ankle $1\frac{1}{4}$.

CASE 9.—D. S., a merchant aged 28, was first seen in July 1930. Intermittent claudication had been present in both legs for two years, and for seven weeks he had a painful ulcer on the right foot. He was smoking twenty cigarettes daily. He was well nourished. The general physical examination was negative. The circulation in the upper extremities was normal. Both femoral pulsations were small, both popliteals absent. There was no pulse in either foot. The right foot was cold and red, and on the dorsal surface there was a necrotic ulcer 3 by 4 cm. in diameter. The oscillometer readings were left calf faint, left ankle 0, right calf faint, right ankle very faint. The patient stopped smoking and was treated with intravenous injections of 5 per cent sodium chloride solution. In February 1931 the ulcer was healed and he could walk four blocks slowly without pain. Treatment was stopped in August 1932. He has been examined regularly every year since then. He has continued in excellent health, without recurrence of symptoms. He has been working regularly. When last examined, in August 1943, there was no pulse in either foot. The oscillometer readings were both calves $2\frac{1}{2}$, both ankles $\frac{3}{4}$.

CASE 10.—L. B., a salesman, was first seen in April 1931, at which time he was 31 years old. He gave a history of intermittent claudication in both legs for one year. He smoked twenty cigarettes a day. He was well nourished. The general physical examination was negative. The circulation in the upper extremities was normal. Both femoral and both popliteal arteries were open. The right anterior tibial and dorsalis pedis pulsations were present. There was a good pulse on the outer side of the right ankle. The right posterior tibial pulse was absent. There was no pulse in the left foot. The left foot presented typical rubor in the dependent position. The oscillometer readings were right ankle 2, left ankle 2. He stopped smoking and was treated with saline injections with diminishing frequency for a year. At this time he was able to walk ten blocks without any pain, and he returned to work. He has been examined periodically, the last time in July 1942. At this time he had no symptoms in his legs. All pulses were present in the right foot. The left anterior tibial pulse was present. There was no other pulse in the left foot. The oscillometer readings were right ankle 3, left ankle $2\frac{1}{2}$. He had never had any recurrence of symptoms.

SUMMARY AND CONCLUSIONS

One hundred patients with thromboangiitis obliterans have been personally followed more than ten years. All these patients stopped smoking at the beginning of treatment and have not resumed since.

In all of them the disease has remained completely arrested following the initial period of treatment.

Thromboangiitis obliterans is caused by smoking in individuals constitutionally sensitive to tobacco.

1126 Park Avenue.

Discovery of Oxygen.—No one could have been more surprised, he tells us here himself, than the large hearted, liberal minded, nonconformist English clergyman Joseph Priestley, whose curiosity actually brought him credit for the discovery of oxygen on Aug. 1, 1774. Always a stubborn believer in the false "phlogiston" theory (which held that heat was a ponderable substance), Priestley called his new gas "dephlogisticated air"; Lavoisier gave it the name "oxygen" and made it a foundation stone of modern chemistry. These early chemists, understandably enough, found difficulty in distinguishing between surprisingly different kinds of new "airs" and "gases." "Empyrical air" was the name given to oxygen by Carl Wilhelm Scheele (1742-1786), a poor Swedish apothecary, discoverer of chlorine, glycerin, barium, ammonia and numerous organic acids, whose posthumous notes reveal that he had prepared oxygen before Priestley.—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

OUTBREAK OF FOOD POISONING DUE TO SALMONELLA MONTEVIDEO IN AN ARMY GENERAL HOSPITAL

VARIED CLINICAL MANIFESTATIONS AND DEMONSTRATION OF SALMONELLA AND HETEROPHILE AGGLUTININS

LIEUTENANT COLONEL JOHN B. D'ALBORA

MAJOR ALFRED P. INGEGNO

AND

CAPTAIN JOHN N. EDSON

MEDICAL CORPS, ARMY OF THE UNITED STATES

This is a report of an outbreak of food poisoning due to *Salmonella montevideo* affecting both the organizational personnel and the patient population of an army general hospital. The clinical features were varied, and isoagglutinins and heteroagglutinins were demonstrated in the blood of infected persons.

The first cases appeared during the night of April 11-12, 1944 with manifestations of an acute, prostrating gastrointestinal disturbance. Within twenty-four hours 267 persons had the ailment. In the next twenty-four hours 70 more cases appeared, and in the third twenty-four hour period an additional 13 cases developed. In all 350 persons were afflicted, and of these 303 were patients. Of the remainder, 45 were enlisted corpsmen and 2 were nurses of the hospital staff. It was found that, of the three hospital messes (officers', enlisted men's and patients') only the patients' mess was implicated. Of the 350 individuals affected 346 had eaten food from that mess, and 3 of the remaining 4 had had contact with food from the patients' mess in serving it or cleaning plates that had contained it. In 1, connection with the patients' mess could not be established.

Food served at supper of April 11 was responsible for the outbreak. All preceding meals could be excluded by virtue of the fact that 39 patients had been transferred to another hospital after lunch of that day, none of whom became sick. Unfortunately, samples of food eaten at the supper meal were unavailable the next morning. This precluded a direct bacteriologic study of the food consumed. However, analysis of the dietary histories of the affected persons permitted the conclusion that at least one of three pans of rice pudding had been the immediate infected source. Preparation of the pudding had been completed by 4 a. m. of April 11. It had then been left in flat field-range pans at kitchen temperature until served that afternoon at 4 o'clock and later. There had been twelve hours or more opportunity for contamination and incubation. Further consideration as to the possible ultimate source of infection is given later.

CLINICAL FEATURES OF OUTBREAK

The extremes of calculated incubation time from the offending meal to the onset of symptoms was from three to sixty-six hours, and more than half began within fifteen hours or less. The onset was abrupt,

with abdominal cramps and watery diarrhea. There were two to twenty liquid evacuations in the first twenty-four hours. Nausea and vomiting were usual, and toxic manifestations in the form of headache, fever, chilliness or chills, generalized aches and pains (particularly of the lumbar region), rapid pulse and a flushed, prostrated appearance were the rule. The abdomen was diffusely tender. Fifty-six patients (about 15 per cent) had herpes febrilis, and this was sometimes pronounced and extensive. The average duration of acute symptoms was three to six days, with fever ranging from 102 to 104 F. In a few cases the temperature went above 105 F. The diarrhea lasted three to five days usually but in some cases persisted to a mild degree for as long as a week or more. Almost all of the duty personnel affected had to be hospitalized.

An interesting feature of the outbreak was the occurrence of 19 cases (about 6 per cent) with bronchopulmonary involvement. Of these, 14 showed roentgenographic pulmonary changes interpreted as interstitial pneumonia, 4 had evidence of acute bronchitis and 1 had a frank bronchopneumonic process with bloody sputum which was positive for *Salmonella* on several examinations. In most of the cases with pneumonia the initial acute gastrointestinal phase of the sickness was followed by a period of several days during which the temperature was normal or almost normal. The temperature then rose again, accompanied by complaints of cough, expectoration and chest pain. Physical findings over the chest were usually minimal. Within a week the temperature returned to normal and x-ray evidence of resolution set in.

A number of patients, after the early acute febrile episode, settled down to a week or more of low grade fever. Some of these had evidence of bronchitis, but in others there was no apparent pulmonary complication. Only 1 developed a palpable spleen, and none had rose spots. In contrast to the early mild polymorphonuclear leukocytosis of the acute phase, at this time these patients showed leukopenia with relative lymphocytosis. Another feature of this group was a rather persistent asthenia and a "washed out" appearance, with fleeting aches and pains.

Two patients had bacteremia with blood culture positive for *Salmonella*. Both had evidence of interstitial pneumonia during their course, which tended to be low grade and prolonged. No suppurative foci developed.

One patient, who also had bacteremia, had urticaria about the knees and left elbow which came on ten days after onset and lasted two days. At the height of his bronchopneumonic process the patient with *Salmonella* bronchopneumonia developed three small subcutaneous nodules on the anterior aspect of the left thigh and one on the volar aspect of the right forearm. The former disappeared in a day, but a month later the one on the right forearm was still present. It was 2 to 3 mm. in size, attached to fascia but not to the overlying skin and only slightly tender; the skin was not discolored.

Several patients complained of sharp occipital and cervical pains radiating to the shoulder girdle. Two had similar type pains involving the trunk. These pains, which were interpreted as neuritic or radicular in nature, came on within a few days of onset of the illness and lasted up to a week.

In the entire group of 350 cases there were no deaths, and clinical recovery, although somewhat prolonged in some, was nevertheless complete.

The authors are assistant clinical professor, associate and assistant respectively in the Department of Internal Medicine, Long Island College of Medicine, Brooklyn, on leave of absence. Lieut. Col. M. L. Rakieten and his staff performed the laboratory work and prepared the bacteriophage. Final identification of the organism concerned as *S. montevideo* was reported by the First Medical General Laboratory. Professional officers of the medical and surgical services assisted in the accumulation of data. Capt. Paolo Revera gave aid during the outbreak. Capt. Peter J. Giranito made the x-ray interpretations.

LABORATORY FINDINGS

Stool cultures could not be made on all patients. However, in over 100 cases initial stool culture was found positive for a nonlactose fermenter belonging to the Paratyphosus C group of *Salmonella*. The organism was found to agglutinate with *Salmonella cholerae* suis antiserum and was later more specifically identified as *S. montevideo*. Two patients had the same organism in the blood and 1 in the sputum, as already noted. Urine cultures on several patients were negative. In order to determine whether significant cross infection was occurring, stool cultures were made on a series of patients who had not fallen ill. All were negative. Further, stool cultures were also made on unaffected mess personnel to exclude any subclinical cases or carriers. These too were entirely negative.

Military requirements, necessitating early return to duty, made it impossible to carry out serial stool cultures on a great number of those afflicted. This had to be confined almost exclusively to organization personnel, particularly since these were almost all food handlers. In 28 of these, serial study was uninterrupted and it was possible to note when the stool cultures turned negative. In these 28, stool cultures remained positive for from two to seven weeks after onset of the disturbance, 21 for four weeks or more. By the end of the seventh week all had become negative. It was not at all unusual for one or even two weekly cultures to be negative with a return then to positive. With 2 exceptions all were permitted to return to food handling after three or more weekly stool cultures in succession had been negative. One man, a cook, suspected of a possible chronic carrier state (even though he met the aforementioned criteria), was permanently excluded from food handling. His role as a possible source is considered later.

During the first week of the outbreak, tests were made for the presence of serum *Salmonella* agglutinins in 25 cases. With 1 exception all were completely negative. This man, with serum *Salmonella* agglutinins in a dilution of 1:320, was suspected of being a carrier, as noted later. Subsequent *Salmonella* agglutination tests were carried out in a number of these cases as well as others not tested in the first week. In from three to six weeks *Salmonella* agglutinin titers ranging from 1:50 to 1:800 were found. Subsequent to the sixth week the titers decreased. A number of individuals not affected with the illness were also tested and showed no agglutinins. It was also interesting to find that some patients developed agglutinins for sheep's red blood cells in titers ranging from 1:64 to 1:512. These too showed a rise within the first few weeks, followed by a decrease in strength. However, there was no consistent parallelism in the development or subsidence of *Salmonella* and heterophile agglutinins, nor was any clear correlation with clinical course evident.

TREATMENT

Symptomatic treatment of these patients consisted in complete bed rest, liquid diet and the administration of antidiarrheal medication such as bismuth and paregoric. When dehydration and toxicity were severe, intravenous infusions of glucose in saline solution were given. A few were given castor oil at the onset of the trouble but it had no effect in aborting the process. More than half of the patients were given full doses of sulfaguanidine during the early stages of the illness. There was no appreciable benefit, either in clinical course or in rendering the stools negative more quickly,

as compared with those receiving no sulfonamide therapy. Sulfadiazine was also given to a group of patients in an attempt to turn stool cultures negative more quickly. It was entirely ineffective. In a few cases bacteriophage was given. Its value could not be assessed, although in 2 cases its administration was followed by an immediate change from persistently positive to negative stool cultures.

ULTIMATE SOURCE OF INFECTION

The cook who prepared the rice pudding was closely questioned and gave a history of two to four loose stools daily since 1929. A routine stool culture on him a month prior to the outbreak had been negative. He came down with a perfectly typical attack of food poisoning after an eight hour incubation period. Yet during the first week of illness (April 17) his serum was positive for *Salmonella* agglutinins in a dilution of 1:320 at the same time that *Salmonella* agglutination tests on 24 other individuals were entirely negative. At the same time he showed a heterophile agglutinin titer of 1:128. His isoagglutinins and heteroagglutinins rose to 1:400 and 1:256 respectively and then fell to 1:200 and 1:32. It is entirely possible, then, that this man was a chronic carrier and transmitted infection to one portion of the pudding directly or to the pan in which it was put. His carrier state, if present, was apparently not accompanied by appreciable immunity to the infection. Subsequent more thorough clinical and x-ray study resulted in a diagnosis of spastic colon. Six stool cultures were persistently positive between April 14 and May 20 in spite of two courses of sulfaguanidine (54 Gm. from April 13 to 17 and 60 Gm. from April 20 to 24). On May 23 and 24 he was given a total of 12 cc. of bacteriophage orally. This was followed by four negative stool cultures from May 31 to June 16. Nevertheless, as noted previously, he was entirely excluded from food handling.

Various foods, including the ingredients used in making the rice pudding, were cultured, unfortunately not from the same lots used in making the offending food, for none was available. Powdered and evaporated milk, sugar, egg powder, raisins, bread, water, meat, all were negative. It is not likely, however, that an original contamination of ingredients was the source of trouble, for sufficient heat was used in the making of the pudding to kill effectively any enteric organisms. It seems much more reasonable that inoculation of the food occurred in the twelve hour period during which it was kept in pans at kitchen temperature. Contamination by rodents was not considered probable. This could hardly have occurred after the preparation of the pudding in view of the continuous activity of personnel in the kitchen. An original pollution of ingredients, such as is possible in any storeroom, would probably have been eliminated in the process of cooking, as already noted.

SUMMARY AND CONCLUSIONS

1. An outbreak of food poisoning due to *Salmonella montevideo* affected 350 individuals of the patient population and organizational personnel of an army general hospital.

2. The clinical manifestations included pronounced gastrointestinal upset, severe prostration and toxicity, high fever, herpes (15 per cent), bacteremia (2 cases), neuritis and bronchopulmonary involvement (6 per cent). Of the 19 cases with bronchopulmonary involvement, 14 had interstitial pneumonia, 4 bronchitis and 1 a frank *Salmonella* bronchopneumonia with positive

sputum. Two patients had skin manifestations (urticaria and subcutaneous nodules), and a number of cases showed a postacute phase characterized by low grade fever, asthenia, fleeting aches and pains, and leukopenia with relative lymphocytosis. There were no deaths, and no cross infection occurred.

3. The infection gave rise to both isoagglutinins and heteroagglutinins. These did not necessarily parallel each other nor was there any clear correlation between the development of agglutinins and the clinical course. Salmonellosis may thus be one cause of a positive heterophile agglutination test.

4. Full doses of sulfaguanidine were entirely without effect either in ameliorating the clinical condition or in rendering the stool cultures negative. Sulfadiazine was also unsuccessful in converting positive stool cultures. Bacteriophage was tried in only a few cases and was successful in 2.

5. In a group followed with weekly stool cultures none were positive for more than seven weeks whether treated or untreated. Intermittent stool negativity was not unusual.

6. The immediate source of infection was rice pudding allowed to stand at kitchen temperature for twelve hours or more. The evidence suggests that the cook who prepared the pudding may have been a chronic carrier.

HEPATIC DAMAGE IN INFANTILE PELLAGRA

AND ITS RESPONSE TO VITAMIN, LIVER AND DRIED STOMACH THERAPY AS DETERMINED BY REPEATED LIVER BIOPSIES

THEODORE GILLMAN, M.Sc., M.B., B.Ch.

AND

JOSEPH GILLMAN, M.B., B.Ch.

JOHANNESBURG, SOUTH AFRICA

During the last three years nearly 300 children suffering from acute malnutrition have been admitted to the Non-European Hospital, Johannesburg. More than 60 per cent of these infants manifested the clinical signs of pellagra.

In our experience vitamin therapy has not only failed to save the lives of more than 50 per cent of these children but in many instances we strongly suspected that it aggravated the disease and even hastened death.¹ Trowell,² prominent worker in this field, has also recorded the unresponsiveness of this disease to vitamin therapy, including nicotinic acid. In these circumstances, therefore, it was essential to seek some other method of saving the lives of children suffering from severe malnutrition.

Recent experimental work has revealed that in animals the liver is severely damaged by deficiencies or excesses of vitamins³ by diets containing low con-

centrations of proteins,⁴ by the presence or absence of certain amino acids⁵ or by a combination of these imbalances in the diet. However, Himsworth and Glynn⁶ have stated that there is no positive evidence that the liver in man is affected to any extent or in the same manner by dietary imbalances as has been shown to be the case in laboratory animals. Moreover, György in a recent review⁷ cautions against the premature application of these experimental findings to clinical medicine.

Sydenstricker and his collaborators⁸ have repeatedly suggested that the liver may be implicated in some way in the pathogenesis of pellagra. However, apart from the findings by investigators of some disturbances in hepatic function in pellagrins⁹ and the repeated recording of fatty livers in patients dying from this form of malnutrition who come to postmortem¹⁰ there has hitherto been no reliable evidence of the manner in which the liver may be damaged in pellagra or of the role of the liver in the production of the symptoms of this disease. The fatty liver observed in pellagrins at autopsy has usually been attributed either to the excessive imbibition of alcohol or to the severe diarrhea and secondary infection so frequently encountered in moribund pellagrins.

By a significant improvement in the liver biopsy apparatus described by Iversen and Roholm¹¹ as well as by a modification in the approach to the liver, we have to date performed more than 200 biopsies on human subjects without a single mishap. We are satisfied that this biopsy procedure is safe and that it is an indispensable procedure for diagnostic and research purposes, especially valuable in the study of nutritional diseases, in which we have shown that the pathologic processes affect the liver diffusely.

For the first time it is now possible to assess the degree of liver involvement in dietary deficiencies in man and to determine the response of the liver to various forms of therapy. Opportunities are now available for ascertaining the state of the human liver in the common deficiency diseases and of discovering whether the results of animal experiments are applicable to man. Although our knowledge concerning the production of liver disease in animals by dietary means is still fragmentary, nevertheless information is steadily accumulating to the effect that, under certain conditions, vitamins can aggravate the liver damage,¹² whereas proteins and various lipotropes have a beneficial effect.¹³ Despite this information the majority

of nutritional diseases in man are still universally treated with large doses of synthetic or natural vitamin concentrates.

In previous studies, using material obtained by our biopsy procedure, we have demonstrated that, in adult and infant pellagrins, the liver is invariably damaged,

Fig 1—Liver in a severe case of infantile pellagra on the day of admission to hospital. Note the large fat globules in almost every liver cell (liver of the first category) $\times 320$

even in the early stages of this disease.¹⁴ In infants the liver damage is so severe that it could quite easily account for the majority of the clinical features and of the laboratory findings. From this it became evident that the therapeutic measures should be directed not only to the improvement of the clinical condition but also toward the restoration of normal liver structure. Moreover, it appears from our findings that it may be necessary to base the therapy in these diseases not on the present criteria but rather on others dependent on the nature of the liver structure as disclosed by liver biopsy. This seems particularly desirable since, as we shall demonstrate, the liver is frequently severely damaged at the time when patients treated for malnutrition are discharged as clinically cured.

In view of the confidence which most investigators have placed in specific vitamins for the treatment of malnutrition, it became incumbent on us to discover whether this confidence was justified.

This paper is devoted first toward the description of the histologic appearance of the liver in infant pellagrins on admission to the hospital and secondly to an analysis of the effectiveness of vitamins in the treatment of severe malnutrition. It will be shown on the basis of the reactivity of the liver, that vitamin therapy can be deleterious to these patients and that liver extract and especially dried stomach save the lives of infants and children.

MATERIAL AND METHODS

This study is based on the examination of the liver of 20 children suffering from severe infantile pellagra. The salient features of this disease were edema affecting the upper and lower extremities and, in severe cases, the face, eyelids and genitalia; the edema was associated with pellagrous skin lesions on the legs, buttocks, back, arms and face, gray hair or alopecia, as well as patchy or diffuse dermal depigmentation. The stools were, as a rule, bulky, pale and foul smelling and contained much unsplit fat. The serum proteins, both albumin and globulin, were low and a mild microcytic anemia was common. This severe form of malnutrition is apparently identical with that described by other investigators.¹⁵

Within a few hours of admission to the hospital, liver biopsy was performed. All the patients received a diet which, for their age, was regarded as ideal on present standards. Seven were treated with vitamins orally or parenterally; of these 2 received nicotinic acid 100 mg., thiamine 10 mg. and vitamin C 50 mg. by injection twice daily, together with brewers' yeast and halibut oil by mouth. Five cc. of crude liver extract rich in the Cohn fraction was injected twice daily in another group of 7, while the remaining 6 were fed 10 Gm. of dried stomach (ventriculin) together with 10 cc. of tenth-normal hydrochloric acid once daily. Biopsies were taken of all the infants at weekly or ten day intervals for as long as they remained in the hospital.

The biopsy tissue was fixed in a number of fixatives, chiefly solution of formaldehyde U. S. P. diluted 1:10, Helly-osmic and alcoholic picro-formol. Frozen sections of formaldehyde fixed material were stained for

Fig 2—Liver of same patient as in figure 1 eight days after treatment with riboflavin, nicotinamide and a full ward diet. Note the deterioration in the liver as compared with figure 1. Patient ultimately died.

fat with scarlet red. Figures 1 to 8 are photomicrographs of frozen sections stained with scarlet red and Ehrlich's hematoxylin ($\times 320$).

STRUCTURE OF THE LIVER ON ADMISSION

Using as criteria the amount, distribution and the physical appearance of the fat in scarlet red stained preparations, the livers of infantile pellagrins on admission to the hospital have been classified into three main categories

Fig. 3—Liver in another case of severe infantile pellagra on admission. This liver also belongs to the first category (see text)

In the first category were included 13 of 20 cases. The outstanding feature of these livers was the great abundance of fat distributed throughout the tissue (figs. 1, 3, 6). The fat was in the form of a single large pale-staining globule filling the entire cell. The nucleus was pushed to one pole and the cytoplasm was reduced to a narrow rim compressed against the cell membrane. Almost every single cell was involved in this severe fatty change. In fact, the livers were so fatty that they floated in the fixative. There was no necrosis or hemorrhage. Actually the liver was remarkably avascular. Despite the relatively large pieces of liver available, it was extremely difficult to identify any but the larger radicles of the hepatic veins. The sinusoids were closed, but their position was indicated by the rows of flattened Kupffer cells, which remained fat free except on rare occasions when only a small droplet was observed. The portal tracts were difficult to identify because of the great enlargement of the lobule caused by the massive concentration of fat in the individual cells. In some instances a moderate accumulation of round cells was present in the portal tracts (fig. 6). The reticulum was not thickened. In general the histologic appearance of this type of liver was such that it could be mistaken for perirenal fat.

This liver does not resemble in any way the livers described in acute or chronic carbon tetrachloride poisoning, but it did have a striking resemblance to the livers of rats after two hundred days on the diet of mealie pap and sour milk.¹⁶ This is the type of liver structure encountered in the children who die from infantile pellagra¹⁷ and must therefore be regarded as the most serious type of liver damage.

In the second category 7 livers are included. The livers in this group are not so closely similar to one another as in the first, but in general they had several features in common. In a liver typical of the group almost all the cells contain multiple coarse droplets of fat and many have a single large fat globule characteristic of the first group (fig. 4). The fat is not in the form of fine granules, nor is it localized in one pole of the cell. In many cells large vacuoles are present. The fat is stained very deeply and in many instances resembles colloid of the thyroid follicle. This peculiar staining reaction applies to the large droplets no less than to the small. Fat droplets may be present in the nuclei, which are irregular in size and undergo chromatolysis, especially in the cells situated near the portal tract. The sinusoids are for the most part closed, but here and there they may be seen as narrow irregular clefts lined by flattened Kupffer cells, some of which may contain a few droplets of fat. The portal tracts may in some instances contain a considerable number of round cells; the connective tissue is slightly more abundant than in the normal, and the collagen fibers are swollen. Iron is extremely scanty and, as a rule, is absent from the hepatic cells, although the Kupffer cells may sometimes contain a few irregular clumps at the extremity of their nuclei.

Only 1 of the livers has been classified as belonging to the third category. The reason for creating this category for a single specimen will become evident when the absorption of fat from the liver under treatment is examined. This liver was different from the others for a number of reasons, which will be considered seriatim.

There was a considerable quantity of fat in the liver, but many cells were fat free; the large fat globules

Fig. 4—Liver of same patient as in figure 3 eleven days after treatment with 10 cc of crude liver extract daily. Note reduction in the amount of fat, but many large globules are still present

typical of the first group were absent, but instead the cells for the most part contained dustlike particles of fat which gave to the liver a salmon pink color under low power. However, the largest globules of fat exceeded the size of the nucleus, and there were all intermediate sizes between these and the smallest visible particles

17. Trowell, H. C.: Pellagra in African Children, *Arch. Dis. Childhood* 12: 193, 1937; Infantile Pellagra.²

The fat stained a light yellow; the dense red staining fat was absent. Pigment was very scanty. The portal tracts were accentuated by the accumulation of round cells. The sinusoids were open in many areas, but the Kupffer cells did not contain much fat, as is the case in a comparable liver in adult pellagrins.

Fig. 5.—Liver of same patient as in figure 3 eighteen days after treatment with liver extract. Biopsy taken on day of discharge. Note continued improvement as compared with figure 4. Residual damage still present.

RESPONSE TO THERAPY

We have found the liver of an infant pellagrin to be infinitely more valuable in assessing the prognosis than the clinical picture or the laboratory findings. It soon became apparent that the state of the child on admission not only failed to indicate the gravity of the disease but was frequently misleading. However, an examination of the biopsy material from the liver invariably allowed us to arrive at an accurate prognosis.

Patients admitted to the hospital with a liver of the second category often recover after any therapy in which the diet is improved. Patients with the livers of the first category usually die. Since the clinical condition of the patient is misleading, in our opinion, the crucial test of the effectiveness of any specific therapy for infantile pellagra is the one wherein the therapeutic agent is able to restore to normal a liver of the first category. It is on this basis that we have compared the value of vitamins, liver extract and dried stomach.

Vitamins.—All the patients whose livers on admission were grouped in the first category died, irrespective of the nature of the vitamins administered. Actually, under vitamin therapy the livers deteriorated. A comparison of figure 1, a photomicrograph of the biopsy of the liver on admission, and of figure 2, the liver after eight days' treatment with 5 mg. of riboflavin twice a day and 50 mg. of nicotinamide intramuscularly, reveals that, if anything, the liver after treatment was even worse than on admission. It must be mentioned at this stage that some patients whose livers on admission were classified as belonging to the second category soon became worse on treatment with

brewers' yeast, nicotinic acid and riboflavin. Such patients invariably died.

Liver Extract.—Figure 3 depicts the state of the liver of an infant pellagrin on admission. The large fat globules in the liver cells indicate that this liver belongs to the first category. It is indeed seriously damaged and is comparable with figure 1, the liver of a patient treated with vitamins. At the end of eleven days on liver therapy there is a considerable reduction in the amount of fat in the liver (fig. 4). Many of the cells still contain a single globule of fat, but these are now smaller and stain much more intensely with scarlet red. The nuclei, which in these cells were previously flattened against the cell membrane, have now become round or oval and are diffusely stained with hematoxylin. Medium sized fat globules are present in many cells, while other cells contain large vacuoles, devoid of fat. Numerous cells with a single large fat free vacuole and a flattened nucleus are irregularly scattered throughout the section. The sinusoids are partially open in patches; the Kupffer cells are devoid of fat. The portal tracts are prominent, because of the massive accumulation of round cells.

The liver at this stage has improved as compared with the first specimen (fig. 3) and now belongs to the second category. A third biopsy on the same child eighteen days after admission reveals a further reduction in the amount of fat (fig. 5), but this is not so pronounced as the reduction in fat between the first and second biopsies. Many of the cells still contain single large fat globules, less intensely staining than those seen in the second biopsy. The number of cells without any fat and those with fat free vacuoles has increased; binucleosis is extremely common, and the nuclei are irregular in size and in staining reaction. Many sinusoids are open, and others are in the process of developing patent lumens. The portal tracts still

Fig. 6.—Liver of a third patient with severe infantile pellagra on admission. Degree of damage comparable with figures 1 and 3.

contain large numbers of round cells. At this stage the child was discharged as clinically cured.

It is evident that liver extract has definitely reduced the amount of fat in the liver, but the response is slow. Even when the patient was discharged there was so much residual liver damage that the liver was still classified as belonging to the second category.

Those patients who, on admission, had livers belonging to the second category, when treated with liver extract improved clinically, but even after twenty-one days large fat globules were still present in many of the cells.

From the foregoing it is evident that liver extract can improve a liver of the first category and so remove the fat that the liver now can be regarded as belonging to the second category. Moreover, such treatment can also remove some fat from livers belonging to the second category on admission, but in none of the cases treated with liver extract could the liver be regarded as completely restored when the patients were discharged. It must be mentioned that liver extract is superior to vitamins, as 5 of the 7 infants survived, while in the case of the vitamins all 7 died.

Dried Stomach.—The most dramatic results were obtained with dried stomach. Clinically moribund patients rapidly lost their edema fluid, the skin and oral lesions healed, the diarrhea stopped and the patient recovered within one week. Dried stomach was the only substance so far used by us when the clinical improvement was a reflection of the rapid healing of the liver.

This is well illustrated by the following series of liver biopsies taken from an infant moribund on admission. The first biopsy revealed the liver to be grossly fatty and similar in all respects to the seriously injured livers of the first category (fig. 6). Within ten days there was a sharp reduction in the amount of fat, which at this stage was distributed chiefly in the form of fine particles, with transitions to rather coarse globules exceeding the size of the nucleus (fig. 7). The fat droplets, especially the large variety, stained intensely, as in the livers of the second category, but many cells contained fat stained salmon pink or yellow, as described for the third category. Large vacuolated cells are absent, the sinusoids are patchily dilated and

Fig. 7.—Liver of same patient as in figure 6 five days after the cessation of a five day course of dried stomach. Note the improvement as compared with figure 6, but large fat globules are still present in many liver cells.

there is a moderate accumulation of round cells in the portal tract. Dried stomach is the only substance thus far used with which we have been able to convert a liver of the first category into a type intermediate between the second and third within the short period of eleven days. Moreover although dried stomach was

administered for only five days, at the end of twenty-one days the fat had become reduced still further and only an occasional cell contained fine droplets of deeply stained fat (fig. 8). The cytoplasm was very watery, while the nuclei of the cells related to the portal tract contain a single large clear vacuole; the sinusoids are

Fig. 8.—Liver of same patient as in figure 6 ten days after cessation of a five day course of dried stomach. Note almost complete disappearance of fat from the liver cell. Only a few fine fat droplets remain. Compare with figures 2 and 5.

for the main closed, although here and there they are dilated. The portal tracts still contain small numbers of round cells.

In those patients with a liver belonging to the second category on admission the fat is also rapidly depleted, but at the end of two weeks it is still present in the form of dark red globules distributed in a patchy fashion.

Dried stomach therapy was continued only for five days, but the livers continued to improve even after the treatment was stopped. Although the livers did not return completely to normal, the results so far obtained were infinitely superior to those following the use of liver extract. Our supply of dried stomach was limited, but we feel that an additional five days treatment might have completely removed all the fat from the liver.

Incomplete treatment with dried stomach may also be associated with mild residual damage which may predispose the patient to a relapse. However, the results obtained thus far indicate that dried stomach acts rapidly on the liver and patients invariably respond within forty-eight hours of treatment irrespective of the severity of the hepatic injury.

COMMENT

One of the striking features of infantile pellagra is the consistent presence of extensive fatty changes in the liver. As we shall show later, hepatic damage is also invariably present in adults suffering from pellagra. Such fatty livers in infantile and adult pellagra have been previously reported only at postmortem.¹⁸ By means of the liver biopsy technic we have been able to demonstrate that the liver may become extensively fatty several weeks before death. In no case of infantile pellagra has the liver been free of fat.

The fatty change in the liver has been so extensive, and the circulation through the liver so bad, that to us it seemed the infant was virtually hepatectomized. The

¹⁸ Denton,¹⁹ Trowell,²⁰ Sydenstricker and Thomas,²¹ Trowell.¹⁷

disturbances in blood protein, hemopoiesis and carbohydrate metabolism in pellagra can be easily attributed to the extensive liver damage. However, despite the extensive injury to the liver, jaundice was not observed in a single case under our observation.

The presence of large quantities of unsplit fat in the stools suggested a deficiency of bile in the alimentary tract. However, Shapiro and his associates,¹⁹ using labeled fat, have shown that even when bile is absent from the bowel the dietary fat is absorbed and, when a fat free diet is fed, large quantities of fat are excreted into the bowel. They concluded that the fatty stool in obstructive jaundice is not due to the interference with the absorption of dietary fat. That the bulky fatty stool so commonly encountered in infantile pellagra is probably due to excessive fat excretion receives support from the fact that the dietary fat in these cases is extremely low and could certainly not account for the large amount of fecal fat. Since the diet of these patients is almost pure carbohydrate, it is possible that the accumulation of large quantities of fat in the liver and in the stool is an expression of the conversion of carbohydrate into fat, together with an inability of the tissues to utilize this fat. At postmortem there is a remarkable contrast between the enormous accumulation of fat in the liver and the extreme depletion from the body depots as expressed by the severe emaciation.

During the last three years we have observed over 250 cases of infantile pellagra, of which 50 per cent ended fatally. In the treatment of this large series of cases vitamins were used orally and parenterally together with a diet balanced in respect of proteins, carbohydrates, fats and natural vitamins. Moreover, in some cases transfusions of blood or concentrated serum also were tried. A mortality rate of over 50 per cent in patients on this regimen cannot be regarded as satisfactory, nor does it indicate that the administration of vitamins and the correction of the diet on the basis of current knowledge can save the lives of patients suffering from severe infantile pellagra.

Trowell²⁰ has been so impressed by the resistance of this disease to nicotinic acid and other vitamins that he has recently suggested that the name infantile pellagra, which he originally introduced and which we still accept, be replaced by the term "malignant malnutrition."

Whereas we have shown that nicotinic acid removes the fat from the liver in adult pellagrins, albeit this depletion of liver fat is associated with massive deposition of pigment in most instances,²¹ in children this vitamin appears to intensify the lesion. Since Handler and Dann²² have shown that nicotinamide in large doses produces fatty infiltration in the liver of rats, and in view of our confirmation of this finding in human infants, we arrive at the opinion that nicotinic acid is a dangerous form of therapy in severe cases of infantile pellagra. Our experience with thiamine, riboflavin, pyridoxine and brewers' yeast alone, together or in combination with a wholesome diet and serum transfusion, points to the fact that not only are they not life

saving measures but they may even hasten the death of a patient with severe infantile pellagra.

Sydenstricker and his collaborators,²³ on the basis of their extensive experience, consider that, of all the substances used by them, liver extracts rich in the Cohn fraction are the most rapidly curative of all the manifestations of pellagra. Elvehjem²⁴ stated that, in his opinion, "most of the biological activity of liver can be ascribed to free nicotinic acid or its derivatives." Since we have found that while nicotinic acid intensifies the lesions in our cases, and liver extract rich in the Cohn fraction improved the clinical condition and partially depleted the fat from the liver, it follows that the beneficial effects of the liver extract could hardly be ascribed to the nicotinic acid component alone. Liver extract is apparently rich in numerous substances which are considered to be lipotropic.²⁵ On the other hand, McHenry and Gavin²⁶ reported that the administration of beef liver extract to rats on a fat free diet caused acutely fatty livers, provided thiamine, riboflavin, pyridoxine and pantothenic acid were also supplied. The complex nature of an extract of liver prevents us from attempting to ascribe its beneficial effects to any single known substance. The fact that the clinical condition improves very slowly when liver extract is administered and that even at the end of five weeks some fat is still present in the liver indicates that this form of therapy is still inadequate to effect a complete cure, even in combination with the full diet. Thus, while Sydenstricker and his associates have found that the intravenous injection of liver extract is the most efficient method for the treatment of pellagra in adults, our experience indicates that it is only partially effective in infants.

Prior to the introduction of nicotinic acid a variety of substances were used in an attempt to discover a specific cure for this widespread disease.²⁵ In view of the apparent similarity in the clinical manifestations of pellagra and pernicious anemia, Spies and his associates at first treated pellagrins with gastric juice from normal individuals,²⁶ and then when dried stomach became available through the efforts of Sturgis and Isaacs²⁷ and Sharp²⁸ he used this substance in massive doses (750-1,000 Gm. daily) with good results. Sydenstricker and his collaborators confirmed Spies's observations²⁹ and even went so far as to suggest that pellagra might be due to an intrinsic gastric deficiency unrelated to that described in pernicious anemia.³⁰ Despite these significant observations, Spies as well as Sydenstricker firmly believed that liver extract was the most valuable form of therapy for pellagra.³¹

With the introduction of nicotinic acid these observations became obscured and no great importance was attached to the casual remarks by Spies and Sydenstricker that relapses were rarer after dried stomach than after liver extract and nicotinic acid.

Apparently unaware of the work of Spies and Sydenstricker, Petri³² demonstrated the value of an extract of hog's stomach in the treatment of endogenous or secondary pellagra. Later Bandier³³ reported excellent results in primary pellagra with doses of dried stomach infinitely smaller than those used by Spies.³⁴

From the literature available it would appear that since that time no further reports have been published concerning the value of dried stomach in the treatment of pellagra.

In most countries clinical and experimental medicine today base their practices almost entirely on the doctrine of causality in its simplest form. In the field of nutrition, disease is said to be caused by the presence or absence of specific substances the addition or subtraction of which is believed to cure that disease. In the earliest phases of acute deficiency diseases this approach may have the desired effect. Thus, feeding a wholesome diet may cure a pellagrin, but clinical experience has shown that despite the application of all known forms of therapy 6 per cent of adult pellagrins still die, and among infants the mortality rate may be as high as 90 per cent.

While dietary imbalance may initiate the disease, secondary changes are produced in the body which not only alter the original character of pellagra but may even determine its subsequent course. Once these secondary changes occur, the treatment of pellagra by the routine procedure proves futile. The new character of the disease now demands an analysis of the secondary pathologic process. In these circumstances the treatment will be determined by the nature of these secondary processes.

Having established that in infantile pellagra the liver is invariably injured to a greater or lesser extent, it seemed logical to assist the recovery of the damaged liver by supplying liver extract. While it was possible to effect a clinical cure together with a significant improvement in the liver, the patients left the hospital with residual liver damage.

From this we concluded that liver extract was incapable of completely curing the disease. Moreover, we appreciated for the first time why relapses occurred so frequently in adult pellagrins who on clinical grounds were pronounced as cured after liver therapy.

For this reason we directed our attention to other organs, such as the stomach and the nervous system, which are known to be implicated in this disease and which may initiate and maintain the pathologic processes in the liver.

It is not our object in this study to consider the possibilities of effecting a cure of pellagra through the nervous system, although Speransky has already suggested that this may well be achieved.³⁵

Petri's description of gastropival pellagra in man and in gastrectomized swine³⁶ became significant especially since gastric dysfunction is such a constant finding in pellagrins.³⁷ Moreover, endogenous pellagra originating primarily from gastric damage failed to respond to nicotinic acid but improved rapidly with stomach extracts.³⁶ It seemed, therefore, that pellagra of dietary origin was an expression of disorder of the gastrohepatic complex, and therefore the administration of dried stomach appeared to be a possible way of curing the refractory forms of pellagra in adults as well as in children.¹ The rapid improvement of the clinical condition, the resolution of the edema and the remarkable improvement in the structure of the liver (figs. 6, 7 and 8) leave no doubt in our minds that dried stomach is the most valuable single therapeutic agent available at present for saving the lives of children suffering from severe malnutrition.

In view of the rapid depletion of the large deposits of fat in the livers of infantile pellagrins, stomach extract must be regarded as a vigorous lipotrope. Since we have administered only 10 Gm. of dried stomach daily it is unlikely that this lipotropic action could be ascribed to its choline content. It is possible that the beneficial effects obtained with large doses of liver extract may be ascribed to a factor similar or complementary to that contained in stomach extracts.

One other aspect of the action of this gastric extract requires comment. An outstanding feature of cases of infantile pellagra is a severe and extensive edema. Liver extract produces a slow resolution of this edema. However, after the administration of dried stomach there is a rapid diuresis. Within twenty-four to forty-eight hours the infant may lose anything from 8 to 20 ounces in weight as the result of the rapid depletion of edema fluid. After four to seven days on dried stomach the edema is completely resolved. Dried stomach, therefore, is not only a potent lipotrope, but in these patients it also has a vigorous diuretic action.

From the foregoing it is evident that the liver of infants is severely damaged, even within six to eight months of birth, by dietary imbalance. Owing to the poor economic status of the African, a history of repeated attacks of acute malnutrition is invariably elicited from adult pellagrins. Each attack damages the liver. Cirrhosis has been encountered even in children under the age of 10, and in adults, by repeated liver biopsies, we have observed the development of pigment cirrhosis within six months of an attack of pellagra.

We consider the high incidence of cirrhosis and primary carcinoma of the liver in adolescent and young adult Africans as being due in no small measure to repeated insults to the liver resulting from acute and chronic malnutrition.

SUMMARY AND CONCLUSIONS

1. By means of liver biopsies we have established that, on admission to the hospital the livers of infantile pellagrins show various degrees of fatty change; in

Edlitz, W. H., and Dalldorf, G.: *The Avitaminoses*, ed. 2, Baltimore, Williams & Wilkins Company, 1941.

severe cases almost every liver cell is distended by a single large globule of fat. Liver biopsy is indispensable in establishing the prognosis and in assessing the effectiveness of any form of therapy.

2. The reactions of the liver to vitamins, liver extract and dried stomach have been studied in a selected series of 20 infantile pellagrins with comparable hepatic lesions on admission.

3. In severe cases the administration of vitamins intensified the accumulation of fat in the liver cells. Every one of the 7 cases treated with vitamins terminated fatally.

4. Although liver extract rich in the Cohn fraction is superior to vitamins, the fat is depleted from the liver slowly despite the clinical recovery. Only 2 of the 7 cases in this group ended fatally.

5. Dried stomach in 10 Gm. doses daily in combination with hydrochloric acid leads to spectacular recovery of the patient and loss of edema fluid. Moreover, the fat in the liver disappears rapidly and almost completely in every instance. All the patients treated with dried stomach recovered.

6. Although the fat content of the diet is low, there is a massive accumulation of fat in the liver, and it is excreted in large amounts in the feces despite the emaciation of the rest of the body. It is suggested that, in infantile pellagra, carbohydrate is converted into fat which cannot be utilized.

7. We conclude that the administration of vitamins in severe nutritional edema associated with pellagrous lesions in infants can be extremely dangerous and is contraindicated.

8. On the basis of the results obtained in our carefully selected cases, dried stomach is the most valuable therapeutic agent available for the treatment of severe infantile pellagra. Since dried stomach causes the rapid depletion of fat from the liver, it must be regarded as a vigorous lipotrope.

9. In children discharged as clinically cured, liver biopsy has revealed the existence of residual liver damage, the extent of which is determined by the severity of the initial lesion and the nature of the therapy.

10. Recurrent attacks of subclinical and overt malnutrition result in progressive hepatic damage. These repeated insults are in no small measure responsible for cirrhosis and probably for primary carcinoma of the liver so frequently encountered in young Negroes in South Africa.

Regulation of Body Temperature.—Heat loss can occur through conduction, radiation, convection and vaporization. The amount of heat lost through these four channels depends chiefly on the surface area of the body and the difference between its temperature and that of the surroundings. The temperature of the skin depends on the rate at which blood passes through the cutaneous vessels. Thus vasomotor changes in the skin capillaries are most effective in controlling heat loss by radiation and convection. Heat loss by vaporization of water occurs in the lungs and from the surface of the skin. Any increase in respiratory ventilation augments the heat loss by vaporization from the lungs, while nervous control of perspiration limits the heat loss by evaporation of water from the skin. Thus, the control of heat loss is effected by the interplay of a number of physiologic processes—circulatory, respiratory and nervous in character.—Shock, Nathan W., from *Mental Disorders in Later Life*, edited by Oscar J. Kaplan, Stanford University Press, 1945.

THE EFFECTS OF CONCENTRATED HYPERIMMUNE RABBIT SERUM IN LOUSE BORNE TYPHUS

LIEUTENANT COMMANDER ANDREW YEOMANS
(MC), U.S.N.R.

LIEUTENANT COLONEL J. C. SNYDER
MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

A. G. GILLIAM, M.D.
Senior Surgeon, U. S. Public Health Service
BETHESDA, MD.

The treatment of classic louse borne typhus with immune serum of various types has been described in many reports. Most of the attempts indicated that human convalescent serum had no noticeable effect on the course of typhus. The serums obtained from animals after they had recovered from experimental typhus have also been given a clinical trial, but the reports of the therapeutic value of such serums have been somewhat conflicting. The early literature has been reviewed by Otto and Munter.¹

More recently the development of satisfactory technics for the cultivation of rickettsias in large quantities has facilitated the hyperimmunization of animals. Zinsser, Castaneda and Hager² prepared a serum by inoculation of horses with rich suspensions of murine rickettsias obtained from x-rayed rats. Durand and Balozet, by inoculations with rickettsias from infected lungs of rodents, obtained a hyperimmune horse serum against epidemic louse borne typhus,³ which was reported on favorably in recent therapeutic trials.⁴ Wolman,⁵ after treating 220 patients in Ethiopia with antityphus horse serum, reported that the treated patients had a lower mortality and a shorter illness than the untreated patients. Kurotchkin, van der Scheer and Wyckoff⁶ used infected yolk sacs of developing chick embryos⁷

From the Cairo unit of the United States of America Typhus Commission.

Numerous chemical determinations for the cases in this study were performed by the 38th General Hospital Laboratory staff.

Technical assistance was given by Sergeant Stephens and Corporal Stearman in the laboratory work performed on the serum-treated patients.

The authors received generous cooperation from the officials of the Egyptian Ministry of Public Health, who facilitated the studies of the United States of America Typhus Commission in Egypt.

Serologic tests and strain isolations were performed by Col. Harry Plotz and Capt. Byron Bennett, with the assistance of Sergeant Guin and of Dr. Tabet of the Egyptian Serum and Vaccine Institute.

The director of the Cairo Fever Hospital, Dr. M. A. B. Demerdash Bey, made possible the establishment of the United States of America Typhus Commission ward and laboratory in his institution and gave helpful advice and cooperation.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

to hyperimmunize rabbits. They refined and concentrated the immune serum by a process similar to that used in the production of antipneumococcus serum. Topping⁸ reported that serum prepared in this manner against spotted fever showed definite therapeutic value if treatment was instituted in the first few days of illness. In laboratory studies the refined and concentrated antityphus rabbit serum has shown a striking effect in experimental typhus. The febrile response of guinea pigs,⁹ the death of white mice from several lethal doses of rickettsial toxic substances¹⁰ and the fatal infection of cotton rats¹¹ can be prevented by the hyperimmune serum in high titer. In this regard Felix¹² cited evidence from which he concluded that "the efficacy of a therapeutic antityphus serum depends on the presence in it of effective amounts of the two different antibodies corresponding to the heat labile and heat stable rickettsial antigens." Although the rabbit serum does not contain appreciable amounts of antibodies which agglutinate proteus OX 19, the high concentration of neutralizing and complement fixing antibodies¹³ in this rabbit serum, its striking properties against experimental typhus and the favorable effects of a similar serum against another rickettsial disease of man were considerations which prompted the clinical trial of hyperimmune rabbit serum in typhus. The distinctly beneficial effect observed in patients treated with serum early in the course of louse borne typhus is the subject of this report.¹⁴

In February 1943 the United States of America Typhus Commission, in cooperation with the officials of the Egyptian Ministry of Public Health, established an experimental ward in the Cairo Fever Hospital.¹⁵ The study of the therapeutic effect of hyperimmune rabbit serum was begun near the peak of the epidemic, in April 1943. Twenty-five cases of typhus were treated with varying amounts of serum.¹⁶ For reasons which are not pertinent to this discussion the usual method for therapeutic trials, the alternation of control and treated cases, was not followed. Instead, the 25 treated cases were admitted in consecutive order to the Commission ward. The background of experience during two epidemic years in the Cairo Fever Hospital is drawn on to provide a control group for comparison with the serum treated group. All of the cases discussed in this paper were considered to be certain cases of typhus on the basis of clinical and laboratory evidence. The numerous strains which have been isolated

from the cases in the Commission ward have uniformly shown the characteristics of epidemic louse borne typhus.¹⁷

SELECTION OF CASES

The 25 patients who were selected for serum treatment were unvaccinated Egyptian men in the age group 18 to 48 years who had no obvious complicating conditions at the time of admission, whose date of onset of illness was clear and who were not later in their disease than the seventh twenty-four hours.

Of the 159 patients who were studied in the Commission ward in 1943 and 1944 there were 44 patients who conform to the criteria cited. This group received no special therapy other than nursing care, fluids and appropriate measures to combat complications which arose during hospitalization. For the purpose of comparison with the cases treated with serum, the 44 are designated as the "untreated" control group. Their clinical course was representative of the entire experience of the Commission ward.

The high mortality of the typhus cases in the general wards of the Fever Hospital during the period covered by our observations on serum treatment provides evidence that the typhus epidemic was severe. In May and June 1943 a total of 1,719 Egyptian men aged 18 to 48 were admitted to the general wards of the Fever Hospital suffering from typhus, and of these 393 died, a mortality of 23 per cent. This figure is approximately the same as that for the two entire epidemic seasons, and it indicates that there was no appreciable change in the severity of the epidemic in May and June 1943 which might confuse the observations of the effects of a therapeutic agent.

ESTIMATION OF SEVERITY OF ILLNESS

To facilitate the analysis of cases an arbitrary classification of clinical severity was decided on. After discharge from the hospital each patient was classified on the basis of his clinical course. The principal factors which influenced the estimation of severity were the intensity of subjective symptoms (headache, generalized bodily aches and pains, tinnitus, deafness); the degree of prostration; the extent of central nervous system involvement (mental dulness, stupor, coma, incontinence of urine and feces, abnormal neurologic signs); the severity of cardiovascular system involvement (hypotension, tachycardia, peripheral vascular failure, myocardial damage); and, finally, the occurrence of urinary retention, oliguria, nitrogen retention, bronchopneumonia, otitis media, parotitis, furunculosis and gangrene. With these factors in mind the following classification was made:

A. Cases so mild that a definite diagnosis of typhus on clinical evidence alone was not possible, the final diagnosis being made only with the aid of positive laboratory data.

B. Cases with minimal symptoms and signs, yet definitely diagnosed as typhus on clinical evidence.

C. Cases of moderate severity, showing slight prostration, central nervous system involvement, cardiovascular changes or mild complications.

D. Severe typhus cases, with definite prostration, central nervous system involvement, cardiovascular changes or serious complications.

14. A recent paper has been published by R. S. Stevens (Louse-Borne Typhus Fever: Trial of Serum Treatment, *Lancet* 1: 106-109 [Jan 27] 1945) concerning the treatment of 7 unvaccinated patients with typhus among British army personnel by hyperimmune antityphus rabbit serum. The serum administered to these patients and supplied by Brig General L. A. Fox, Field Director, United States of America Typhus Commission, was the same as that used in our studies. The author's conclusions as to the effect produced by the early administration of this serum in louse borne typhus are in general agreement with our findings.

E. Cases of such severe illness that a fatal outcome was expected at some point in the clinical course.

F. Fatal cases.

PLAN OF TREATMENT

Each patient was tested for sensitivity by the introduction of 0.1 cc. of undiluted rabbit serum into the skin of the forearm. After an interval of twenty minutes the test was observed, and, if negative, serum therapy was begun. Serum was given intramuscularly or intravenously or by a combination of the two routes. The different methods and varying dosages used in the treatment of the first cases reflect the difficulties encountered in our attempts to decide what amount of serum should be given and over what period of time therapy should be maintained. A plan of treat-

As soon as it was observed that such a rate of injection produced no serious effects, it was increased, and maximum being 4 cc. per minute. However, in each case in which serum was administered intravenously for the first time the initial rate did not exceed 0.5 cc. per minute for the first 5 cc. injected.

Chills of varying intensity occurred during seven injections. At the onset of each chill the rate of injection was reduced. It was not found necessary to discontinue any injection because of this reaction. In 1 case severe chills occurred on two occasions from one to three hours after administration of serum. It is our opinion that these reactions were most probably due to imperfectly prepared glassware and were not dependent on any substance in the serum itself.

* Unvaccinated Egyptian men in the age group 15 to 45 who were admitted to the Commission ward in the first week of illness.

† The isolation of strains and the serologic tests were performed by Colonel Plotz and Captain Bennett.

‡ Rectal temperatures were taken at four hourly intervals on all of the patients in this study. A temperature above 37.5 C. (99.5 F.) is considered evidence of fever.

§ Values of the blood nonprotein nitrogen above 45 mg. per hundred cubic centimeters are regarded as evidence of nitrogen retention.

ment gradually evolved which seemed to be satisfactory. It was as follows: The initial dose was 1 cc. of serum for each pound of body weight, half administered intravenously and half intramuscularly. The second and third doses were each 0.25 cc. per pound of body weight and were administered intramuscularly twenty-four and forty-eight hours after the initial dose. It was thought that this plan of treatment would maintain a relatively high concentration of the rabbit serum in the patient's blood stream for several days.

OBSERVATIONS DURING THE ADMINISTRATION OF SERUM

When serum was given intravenously, the blood pressure, pulse and respirations were recorded at short intervals. Subjective and objective effects of the introduction of serum were noted.

Intravenous injections of serum were made at varying rates. At the outset the rate was 0.5 cc. per minute.

Vomiting occurred during one injection. This was coincidental with a fall of 24 mm. in systolic and of 20 mm. in diastolic blood pressure. Nausea occurred in 2 cases; in 1 of these there was a coincidental drop in blood pressure from 96/50 to 80/40.

A fall in blood pressure, not exceeding 25 mm. in systolic and 20 mm. in diastolic, occurred in 3 cases.

The onset of headache or the increase of headache was observed during eleven injections. This headache was frontal in type. On occasions it appeared to be related to the speed of injection.

Suffusion of the conjunctivas was seen during four injections. It was accompanied by headache, or increase in headache, and disappeared promptly when the injection was finished.

Extrasystoles were observed during two injections. In 1 of these cases the irregularity had been noted before the administration of serum was begun. Extrasystoles were noted only during injection in the other case.

Urticaria was noted in 1 case. The skin test was negative. After the injection of approximately 40 cc. of serum in twenty-two minutes several large round urticarial wheals with red bases but no pseudopods appeared on the trunk and limbs. The injection was completed (10 cc. more) and no further reactions occurred.

The skin test in 1 case was thought to give a questionably positive reaction. There was swelling of the wheal with a red base, and one pseudopod. This type of reaction was not considered a contraindication to therapy, and subsequent injection was not accompanied by any further reaction.

Intramuscular injections of serum were given into the buttocks. The greatest amount given by this method was 115 cc. in twenty-four hours. Aside from temporary swelling and tenderness in this particular case, no unfavorable reactions to intramuscular injections were noted.

DOSAGE

The total amount of serum given to each patient varied from 51 to 512 cc. The average dose for the 25 patients was 186 cc. The duration of serum therapy and the total amounts given by intravenous and intramuscular routes appear in table 1.

TABLE 2.—*The Individual Ages, Duration of Fever and Clinical Severity of 44 "Untreated" Control Cases Arranged According to the Day of Illness at the Time of Admission to the Commission Ward**

* Unvaccinated Egyptian men in the age group 18-48 who were admitted to the Commission ward in the first week of illness.

† "Day of Disease." For the 44 control cases this refers to the day of illness at the time of admission to the Commission ward. For the 25 serum treated cases, it refers to the day of illness at the time serum treatment was first begun; two patients (18 and 20) were admitted to the Commission ward one day before serum treatment was started. All of the other patients received treatment on the day of admission.

‡ The duration of fever of fatal cases is not included in the table.

RESULTS OF SERUM TREATMENT

The data obtained from the entire group of serum treated cases are presented in table 1, in which the patients were arranged according to the duration of illness at the time treatment was first started.

Table 2 presents data on the individual ages, duration of fever and clinical severity of the "untreated" control

cases. The various aspects of these tables will now be discussed.

Effect on Clinical Severity.—The clinical severity of the 25 cases treated with serum is compared with the 44 "untreated" control group in table 3. There was only 1 mild (A or B) case in the "untreated" group,

TABLE 3.—*Comparison of the Clinical Severity of 44 "Untreated" Patients* and 25 Patients* Treated with Concentrated Hyperimmune Rabbit Serum*

	Number and Percentage of Patients in Each Classification

Classification of Severity	Average Duration of Fever	
	44 "Untreated" Cases, Days	25 Serum Treated Cases, Days
A.....	..	7
B.....	18	10½
C.....	15	12½
D.....	19½	15½
E.....	23½	19
F.....	(13)	..
Average of all cases except F.....	18½	13

* Unvaccinated Egyptian men in the age group 18 to 48 admitted to the Commission ward in the first week of illness.

whereas the serum treated group contained 1 A case and 7 B cases. There were no deaths among the serum treated group; 8 control patients died. The relative percentages of C, D and E cases were approximately the same in the two groups.

Effect on the Average Duration of Fever.—The average duration of fever for treated and control groups is shown in table 4. The treated patients had an average febrile period of thirteen days, as contrasted with eighteen and one-half days for the "untreated" control patients.

Relation of Duration of Illness at the Time Serum Was Started to the Clinical Course of the Patients.—The importance of early treatment can be seen in table 5, which shows the clinical severity of the 25 serum treated cases arranged according to the duration of illness at the time therapy was first started. Ten cases were treated in the second and third days of illness; 1 was an A case, 6 were B cases, 2 were C cases and 1 was a D case. These results are in sharp contrast to the 15 cases whose therapy was begun after the third day of illness; of these 1 was a B case, 6 were C cases, 5 were D cases and 3 were E cases. In the latter group the principal difference from the "untreated" control group was that there were no fatal cases. Otherwise the distribution of clinical severity was almost identical.

The Effect of Serum Treatment in Relation to the Age of the Patient.—The average age of the serum treated patients in each clinical classification is com-

pared with the corresponding figures for the "untreated" control group in table 7. There was no appreciable difference in average ages which might account for the high incidence of mild cases in the serum treated group.

Effect on the Rash.—Among the 5 patients who received serum in the second day of illness there were 2 who did not develop a rash and a third who had very questionable macules for one day only. All the other serum treated cases developed a characteristic typhus rash.

Effect on Kidney Function.—The blood nonprotein nitrogen was determined in 23 of the serum treated cases. Values above 45 mg. per hundred cubic centimeters were observed in 6 cases, or 26 per cent (table 1). In the "untreated" control group values above 45 mg. per hundred cubic centimeters occurred in 44 per cent of the patients from whom data were available.

Occurrence of Serum Sickness.—Seven patients in the group developed mild serum sickness. Two other patients had transient discomfort which was probably a manifestation of very mild serum sickness.

Isolation of Strains.—In most of the cases the attempt was made to isolate rickettsias from the blood of the patients before serum was administered. Positive febrile responses in guinea pigs were reported from 18 patients (table 1). On several occasions, positive results were obtained from the inoculation of blood which was drawn after varying amounts of serum had been given. In 1 instance, patient 4, the isolation of a strain helped to establish the diagnosis, since the clinical picture was too mild for a definite diagnosis of typhus.

TABLE 5.—Comparison of the Clinical Severity of 25 Serum Treated Cases* with the Duration of Illness at the Time Serum Treatment was Started

TABLE 6.—Comparison of the Clinical Severity of 25 Serum Treated Cases,* with the Average Amount of Serum Administered

Average Number of Cubic Centimeters of Serum Given to the Patients in Each Classification					
A	B	C	D	E	F
150	191	165	263	93	..

* Unvaccinated Egyptian men in the age group 18 to 48 admitted to the Commission ward in the first week of illness.

Relation of the Total Amount of Serum to the Clinical Course.—The average amount of serum which was administered to the patients in each clinical classification appears in table 6. The 3 cases classified as E were among the first 5 in the treated series. An average of 93 cc. of serum was administered whereas in the other groups the amount was from 150 to 263 cc. One of the 3 E cases was treated with a single intravenous dose of 78 cc. as a trial of that particular plan of therapy.

The other 2 E cases presented oliguria and nitrogen retention very early in the illness, and it was considered inadvisable to administer more serum. All of the serum available to us contained 0.4 per cent phenol as a preservative. Since phenol might result in further impairment of renal function, it was our opinion that more

TABLE 7.—Comparison of the Ages and Clinical Severity of 44 "Untreated" Patients* and 25 Serum Treated Patients*

* Unvaccinated Egyptian men in the age group 18 to 48 admitted to the Commission ward in the first week of illness.

serum should not be given to these 2 patients whose renal function was in a precarious state. These considerations show why in the 3 E cases less serum was administered than in the other cases in the study group. The question arises, however, whether more serum might not have lessened the severity of these 3 cases. In the other groups there was no obvious correlation between total amount of serum and clinical severity. Treatment with massive doses continued for several days did not seem to yield better results than the usual plan as described.

Contraindications to Serum Therapy.—A possible contraindication has been mentioned in the preceding paragraph, that is, the administration of large quantities of serum containing phenol or other preservatives which may exert a harmful effect on kidney function when oliguria and nitrogen retention have already made their appearance. The gravity of impaired renal function in the prognosis of typhus is discussed in a separate Typhus Commission report.¹⁸ It is sufficient here to state that in our opinion phenol as a preservative should be avoided in the preparation of antityphus serum in view of the high incidence of impaired renal function in typhus.

COMMENT

The effect of hyperimmune antityphus rabbit serum in the treatment of typhus seemed to be very closely related to the duration of illness at the time treatment was first started. The results with 10 patients treated on the second and third day of the disease were almost uniformly good. When therapy was begun in the fourth, fifth and sixth days of illness it was more difficult to be certain that serum had influenced the course of the disease. To be sure there were no fatal cases, but a very much larger series of treated cases would be needed to prove that serum treatment did reduce mortality. If patients are first treated even later in

18. Yeomans, A.; Snyder, J. C.; Murray, E. S.; Ecker, R. S., and Zarafonitis, C. J.: Azotemia in Typhus Fever, to be published.

their disease than the sixth day, it is probable that the effect of serum would be impossible to evaluate except on a statistical basis.

What are the indications for the use of hyperimmune rabbit serum? The limited supply which is available at the present time precludes its use on a wide scale in an epidemic. Another therapeutic agent, para-aminobenzoic acid, has recently been reported to have a favorable influence on the course of typhus¹⁹ and from the data available it seemed that para-aminobenzoic acid had a somewhat more definite effect in the fourth, fifth and sixth day cases than did the rabbit serum. Since para-aminobenzoic acid is far less difficult to obtain than the hyperimmune rabbit serum, the question arises whether serum treatment should be considered at any time. Its most logical use would be the treatment of medical and sanitary personnel who have been infected with typhus. Such patients are likely to come under medical observation very early in their disease, at the optimum time for serum treatment. However, the widespread use of killed rickettsial vaccines for medical and sanitary personnel is now entirely feasible, and recent experience with Cox type vaccine clearly indicates that the persons who contract typhus after the recommended course of vaccine²⁰ have a mild form of the disease. Up to the present time no proved fatal cases have occurred after the recommended vaccination. On the other hand, the mortality from typhus rises rapidly as the age of the patients increases. It would be overoptimistic to anticipate that vaccine will protect all persons in the age groups above 40 from a serious or even fatal outcome. In the case of medical or sanitary personnel older than 40 every possible attempt should be made to reduce the severity of the disease. The use of hyperimmune rabbit serum, particularly if the course of vaccination has been incomplete or not given at all, is certainly warranted for older patients, for whom it might prove to be a life saving measure.

SUMMARY AND CONCLUSIONS

Twenty-five patients with louse borne typhus were treated with refined and concentrated hyperimmune antityphus rabbit serum. Their clinical course was contrasted with that of 44 "untreated" cases.

The 10 patients who received serum in the first seventy-two hours of illness had mild uncomplicated typhus of short duration.

The 15 patients who had been sick for four, five or six days before serum was administered did not show a striking difference in clinical severity from the "untreated" controls, except that there were no fatal cases.

It is concluded that hyperimmune antityphus rabbit serum has a favorable therapeutic effect on the course of typhus if treatment is started in the first three days of the disease. Although serum treatment seemed to have reduced the mortality in the group of patients who received serum in the fourth, fifth and sixth days of illness, the value of serum therapy for late cases cannot be determined definitely from the data of this study.

INTESTINAL PARASITE SURVEY OF REPATRIATES FROM THE FAR EAST

MAJOR HARRY MOST

MEDICAL CORPS, ARMY OF THE UNITED STATES

There has been considerable speculation and perhaps unwarranted alarm concerning the probability of the importation of various parasites from the tropics into the United States during the postwar period, both by returning military personnel and by relocated civilian population groups. It would seem desirable, therefore, to survey representative groups of these individuals at convenient times and locations prior to their return to normal activities throughout the country in the post-war period.

Early in December 1943 the *Gripsholm* brought more than 1,000 Americans back to this country from the Far East. Among the passengers were several hundred missionaries with many years' residence in China, Japan, Korea and the Philippines. A considerable number of the passengers had been in Japanese occupied territory and in concentration camps for variable periods of time. Sanitary conditions were not always ideal, and opportunities for acquiring intestinal parasites were good.

It occurred to me that it might be profitable and interesting to carry out a survey on all the passengers when they arrived in New York City. Unfortunately, suitable arrangements for this could not be completed. However, by cooperation of several mission boards and many passengers who were canvassed by mail during their stay in New York, it was possible to obtain stool and blood specimens from 144 of the passengers.

PROCEDURE

Patients were requested to collect a casual stool specimen to be stored on ice and instructed to report for examination the following morning, immediately after having taken a saline cathartic (30 Gm. of sodium or magnesium sulfate). The precathartic specimens were stored in the ice box for subsequent study by the zinc sulfate centrifugal flotation method. Three post-cathartic specimens were collected and examined with saline solution and iodine as direct fecal films. In addition, these specimens were concentrated by zinc sulfate centrifugal flotation. Postcathartic specimens containing trophozoites of amebas were stained by Johnson's iron hematoxylin method for corroborative species identification.

Fresh fecal material was cultured on various selective mediums for pathogenic intestinal organisms. The parasitologic studies were conducted in the Tropical Diseases Diagnostic Laboratory of the New York City Health Department, and the bacteriology in the enteric laboratory.

RESULTS

Intestinal Parasites.—Seventy per cent of the passengers examined in this survey were found to harbor one or more intestinal parasites, protozoa or helminths, or both. The various parasites which were discovered, and their incidence are summarized in table 1.

From the Tropical Diseases Diagnostic Laboratories, New York City Health Department.
This study was begun and completed prior to the author's entrance into military service.

doubly ligated at the point of its origin from the aorta. When this was done the thrill and bruit ceased completely. On ligation of the artery the pulse rate dropped from 84 to 72, and the blood pressure rose from 136/60 to 156/100. The innominate artery distal to the fistula was then doubly ligated (fig. 4). It was not thought feasible to ligate the left innominate vein or the superior vena cava. Complete excision of the fistula would have required ligation and division of both innominate veins, the superior vena cava and the innominate artery, and because of the fear of cerebral edema this procedure was not carried out. The operation was discontinued at this time with the hope of eliminating the fistula, since there are no branches of the innominate artery which might communicate with it.

The portion of the sternum with the attached first rib was replaced and sutured with two wires of tantalum (fig. 5). The musculocutaneous flap was replaced with interrupted sutures of silk. At the end of operation the pulse rate was 68 and

tion of the heart on Feb. 15, 1945 showed a transverse diameter of 13.1 cm, a reduction of 2.1 cm. (fig. 3). The venous pressure in the cubital veins on that date was 154 mm. of water on the left and 234 mm. on the right. There is no

Fig 7—Nutrition and movement of the shoulder.

dysfunction of the hand, arm or shoulder movements (figs. 6 and 7). Examination on May 17 failed to reveal any bruit or thrill, and it is believed that the condition is cured.

Rectal Anesthesia.—The production of anesthesia by the intestinal route was attempted shortly after sulfuric ether became more generally available as an inhalation anesthetic agent. Apparently, Nikolas Iwanowitch Pirogoff, the famous Russian surgeon, first described this method in 1847. Sutton said that Pirogoff's original plan was to introduce liquid ether into the rectum. Magendie warned him that this might be a dangerous procedure. Pirogoff then devised a method of vaporizing the ether by heating it and administering it in its volatile form—Keys, Thomas E.: The History of Surgical Anesthesia, New York, Schuman's, 1945.

4. Physicians must consider the possibility of parasitism in evaluating patients' complaints and should resort to stool cultures and examinations for parasites routinely among persons who have served overseas.

5. Zinc sulfate flotation of a casual stool specimen in conjunction with direct examination and zinc sulfate flotation of freshly passed postcathartic specimens is a practical and efficient method for detecting a major number of intestinal parasitic infections in any survey.

Clinical Notes, Suggestions and New Instruments

ARTERIOVENOUS ANEURYSM

THE APPROACH TO THE INNOMINATE VESSELS

COLONEL DANIEL C. ELKIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

Reports of successful treatment of lesions of the innominate artery are rare, particularly those that concern arteriovenous fistula. One of the main problems is the operative approach to the vessels which lie within the thoracic cage and which

in the presence of a communication between them increase the difficulties of proper exposure because of the dilatation of the vessels and the increased collateral circulation always attendant on such a lesion. Most textbooks of surgery describe methods of exposure with a view of ligating the innominate artery by resection of the clavicle and disarticulation of its medial end. This has usually been done for aneurysm of the innominate artery in its terminal portion or as

Fig. 1.—Cardiac dilatation eleven months after injury.

a preliminary to operations on the right subclavian and carotid vessels. This exposure is inadequate in the presence of an aneurysm or a fistula near the aorta. The constant danger of hemorrhage makes an adequate exposure imperative. Splitting the sternum to the third interspace and retraction of the divided portions, as is used in an approach to the thymus gland, would give good exposure, but in the presence of a fistula, with the danger of hemorrhage from dilated, thin-walled vessels, the approach described here is believed to be preferable.

Arteriovenous fistula, innominate vessels, produced by stab wound Nov. 11, 1943. Resection of clavicle, second rib and cartilage. Division of sternum and partial resection. Proximal and distal ligation of innominate artery. Ligation and division of right innominate vein. Recovery.

A soldier aged 25 was stabbed in the right upper chest with sharp-pointed barber scissors on Nov. 11, 1943. There was considerable bleeding from the wound. He became unconscious and was treated for shock by plasma and blood transfusion. Four days later he had apparently recovered and was returned to duty, which he carried out without difficulty or complaint. In the course of an examination on April 1, 1944 a murmur

was discovered in the anterior chest, and for this he was hospitalized and eventually transferred to Ashford General Hospital Nov. 6, 1944. He had no complaints except dyspnea on exertion.

There was a small healed wound on the anterior chest wall just below the right clavicle and 1 inch lateral to the sternal border. In this region there was a well defined continuous thrill, which was felt less distinctly in the neck and along the clavicle. A loud continuous murmur, intensified in systole, was audible. This was transmitted over the entire anterior chest and both shoulders and into both sides of the neck. It was heard over the back of the thorax. The blood pressure in the left brachial artery was 130/50 and in the right 140/40. The venous pressure in the left and right cubital veins was 210 mm. and 220 mm. of water respectively. The thrill and bruit could not be obliterated by pressure. A teleroentgenogram of the heart on October 2 showed a transverse diameter of 16.3 cm. (fig. 1) and after a month of rest this decreased to 15.2 cm. (fig. 2).

Fig. 2.—Reduction in cardiac size following one month of rest.

On Jan. 18, 1945 operation was performed. An incision beginning at the middle of the clavicle was carried medially to the sternum and downward to the fourth rib. The skin with the pectoral muscles was reflected laterally. The inner half of the clavicle was resected subperiosteally, disarticulating it at the sternoclavicular joint. The second costal cartilage and about 2 inches of the second rib were resected. By blunt dissection the space beneath the manubrium sterni was entered and the right portion of the manubrium was divided, leaving its connection with the first rib. A portion of the right half of the manubrium was removed with a rongeur. The pleura was dissected back by blunt gauze dissection from the midline

under the sternum, and the first rib with the attached portion of the manubrium was retracted upward and outward (fig. 4). The internal mammary artery and vein, with their branches, were ligated and divided, and the fat and remains of the thymus were removed. This disclosed the innominate vessels. After considerable dissection a fistula was found to exist between the innominate artery and the two innominate veins at their point of junction just above the arch of the aorta.

Fig. 3.—Return to normal cardiac dimensions one month after operation.

Both veins were greatly dilated, as was the artery proximal to the fistula, and in addition there was a false sac produced by local dilatation of the veins at the point of the fistula.

The right innominate vein distal to the fistula was ligated and divided. The false sac was separated from the aorta, to which it was firmly bound, and the innominate artery was

doubly ligated at the point of its origin from the aorta. When this was done the thrill and bruit ceased completely. On ligation of the artery the pulse rate dropped from 84 to 72, and the blood pressure rose from 136/60 to 156/100. The innominate artery distal to the fistula was then doubly ligated (fig. 4). It was not thought feasible to ligate the left innominate vein or the superior vena cava. Complete excision of the fistula would have required ligation and division of both innominate veins, the superior vena cava and the innominate artery, and because of the fear of cerebral edema this procedure was not carried out. The operation was discontinued at this time with the hope of eliminating the fistula, since there are no branches of the innominate artery which might communicate with it.

The portion of the sternum with the attached first rib was replaced and sutured with two wires of tantalum (fig. 5). The musculocutaneous flap was replaced with interrupted sutures of silk. At the end of operation the pulse rate was 68 and

tion of the heart on Feb. 15, 1945 showed a transverse diameter of 13.1 cm., a reduction of 2.1 cm. (fig. 3). The venous pressure in the cubital veins on that date was 154 mm. of water on the left and 234 mm. on the right. There is no

the blood pressure 140/82. The operation required seven hours. The hand and fingers were warm at the end of the operation and have remained so. Recovery was uneventful except for an accumulation of blood beneath the pectoral muscles, which was removed by aspiration on three occasions. At no time during the patient's convalescence was the temperature elevated above normal, and the highest pulse rate was 100. Examina-

PHYSICIAN VETERANS**VICTOR JOHNSON, M.D., Ph.D.
CHICAGOLIEUTENANT COLONEL HAROLD C. LUETH
MEDICAL CORPS, ARMY OF THE UNITED STATESAND
F. H. ARESTAD, M.D.
CHICAGO

The analysis of the educational desires of over 21,000 medical officers published by Lueth¹ now makes possible an estimate of the probable required expansion of present teaching facilities. The previous tentative estimates based on questionnaires returned by only 1,000 medical officers² require some revision on the basis of the greatly increased information.

**EDUCATIONAL DESIRES OF MEDICAL OFFICERS
AFTER DISCHARGE**

The Committee on Postwar Medical Service³ has been concerned with the problems which will confront the discharged medical officer when the war is won. A major project of this committee has been a questionnaire survey of 60,000 medical officers in the armed forces to determine the additional education they will desire. Table 1, modified from Lueth,¹ summarizes

TABLE 1.—*Future Educational Desires of Medical Officers
by Graduation Groups*

Before 1920.....	394	143	88	625	3.0
Totals.....	3,932	4,563	12,534	21,029	100.0

the results of 21,029 returns by graduation groups. There were 3,932 officers (19 per cent of those replying) who request no further training, 4,563 (21 per cent) who want review or refresher courses of less than six months' duration and 12,534 (60 per cent) who will seek work of six months or more, primarily in residency-type house officerships.⁴ In general, most of those in the older age groups expect either no further training or review and refresher courses lasting less than six months. The more recent graduates are pri-

marily interested in hospital work of six months or more. These findings were to be expected, although the large total numbers desiring advanced medical education, especially for the longer period, could not have been anticipated without the information received directly from the officers themselves.

HOUSE OFFICERSHIPS

In table 2 are analyzed the 12,534 requests for residency-type training in the various fields of medicine listed. About 70 per cent of the officers wanting training of more than six months' duration will seek it in the following four fields: Surgery and its subspecialties (3,497), Internal Medicine and its subspecialties (2,519), Obstetrics and Gynecology (1,353) and General Review (1,351). The fields indicated by the fewest (less than 100) officers are the following: Industrial and Insurance Medicine (14), Hospital Administration (15), Plastic Surgery (75), Neurological Surgery (76) and Public Health (87).

How may these requests for training from the replies of about 21,000 officers be translated into the probable demand from the total of 60,000 officers in the armed forces? There is no generally acceptable formula or statistical procedure for answering this question. Presumably the officers most interested in further training took the trouble to reply, but there may be considerable numbers wanting more education who could not or did not return the questionnaire. Perhaps it is justifiable to assume that the number of officers who indicated a desire for further work but who will be unable or unwilling to carry out their plans will be about equal to the number among those who did not reply to the questionnaire but who will actually seek advanced training when the time arrives. Should this be the case, we could consider the figures in column A of table 2 to indicate the approximate total house officerships required in all fields to meet the needs of all medical officers in all services on their separation from active duty.

REQUIRED EXPANSION OF EXISTING FACILITIES

In addition to returning medical officers, new generations of civilian graduates will seek advanced training. In the year 1941 there were 5,256 residents in the various fields of medicine, as indicated in column B of table 2. Together with the 12,534 medical officers, this totals 17,790 house officerships (column C) required after the war. Since there were 5,796 approved residencies, assistant residencies and fellowships in 1943 (column D), it might appear necessary to provide a total of the nearly 18,000 house officerships as listed in column C.

However, this staggering number, representing a tripling of the normal prewar number of places, would be required only if all medical officers should be discharged at once, which obviously will not be the case. Should demobilization extend over an appreciable period of time beyond the end of the war, the figures listed in column F would indicate the facilities required in addition to those now available. This expansion requires approximately a doubling of the existing house officer positions. In column G is estimated the per cent expansion required in all the fields of medicine.

Some of these percentages of column G may be misleading. The 458 per cent expansion required in General Review courses does not take into account that 721 civilian hospitals now approved for internships are

This report is based on studies by the Council on Medical Education and Hospitals of the American Medical Association and the Committee on Postwar Medical Service.

1. J. A. M. A. 127:759 (March 31) 1945.

2. J. A. M. A. 126:253 (Sept. 23) 1944.

3. The Committee on Postwar Medical Service was organized by the American Medical Association in collaboration with the American College of Physicians and the American College of Surgeons. In addition, it includes representatives of the Association of American Medical Colleges, the Surgeons General of the Army, Navy and Public Health Service, the Veterans Administration, the Federation of State Medical Boards, the American Hospital Association, the Catholic Hospital Association, the Procurement and Assignment Service and the Advisory Board for Medical Specialties.

4. It cannot be assumed that these proportions will apply to all 60,000 medical officers. See discussion in the adjoining column.

also approved for mixed residencies. These plus the 154 mixed residencies in approved hospitals should be ample to provide for the additional 705 places required for General Review residencies or "second year" internships. The 650 per cent increase indicated in Plastic Surgery must be qualified by the fact that the number of places required is small: only about 39 additional openings seem to be needed.

of officers (1,946) failed to specify the field in which they intend to qualify for certification. The smallest numbers (about 200 or less in each field) aim at certification in Neurologic Surgery (80), Plastic Surgery (93), Pathology (201) and Anesthesiology (207). Since there were even more officers who stated that they want certification (13,333) than will want training of six months or more (12,534), it follows that a

1. J. A. M. A. 116:1070 (March 15) 1941.

2. J. A. M. A. 122:1119 (Aug. 14) 1943.

Apart from these two special cases the fields requiring more than twice the 1943 facilities are Surgery and Subspecialties (137 per cent expansion), Dermatology and Syphilology (132 per cent) and Obstetrics and Gynecology (122 per cent). Internal Medicine and Subspecialties, involving large numbers of individuals, will require some 84 per cent increase in 1943 house officerships.

The least expansion of residency places would seem to be indicated in Neurological Surgery (23 per cent), Psychiatry and Neurology (36 per cent), Pathology (41 per cent), Anesthesiology (55 per cent) and Radiology (55 per cent).

SPECIALTY CERTIFICATION BY THE AMERICAN BOARDS

Since over 10,000 medical officers will seek residencies in definite specialties after the war, it is of interest to estimate the number of medical officers who intend to seek board certification. These figures are given in table 3, derived from Lueth's studies. The first column shows the numbers of physicians certified by the various American boards to March 1, 1945, the total being 24,752. In the second column are tabulated the numbers of officers who state that they will seek certification, totaling 13,333. Over half of these (56 per cent) expect to qualify for the American Boards in Surgery (3,450), Internal Medicine (2,644) and Obstetrics and Gynecology (1,368). A large number

goodly number of them already have considerable credit toward the requirements of the boards.

Should these projected certifications be consummated, there will be a decided increase in the number of

specialists in the next few years. It is beyond the scope of this paper to venture an estimate of the consequences of this trend on medical practice and care in this country or to conclude whether the trend should be encouraged or discouraged.

REVIEW AND REFRESHER COURSES

In table 4 is given a further analysis of the desires of medical officers compared with the facilities available for review and refresher courses of six months or less in duration. Included in this group are 860 officers who will want courses of three months or less in duration. Various educational institutions in the year 1943-1944 provided 233 such courses for 26,359 physicians in the various fields indicated. In virtually every specialty it would appear, on superficial examination, that existing facilities might perhaps meet the demands of the returning medical officers in these shortest courses. However, a word of caution is necessary. On the one hand, many of the 860 officers may wish training of nearly three months' duration. On the other hand, over 92 per cent of the physicians enrolled in the very short 1943-1944 courses attended for about two months or less and over

tutions with well organized postgraduate medical courses, and the larger clinics and hospitals. Externships and courses similar to those projected by the University of Wisconsin⁵ and Northwestern University⁶ are being developed by a number of schools. Semiannually the Council on Medical Education and Hospitals of the American Medical Association compiles and publishes a list of continuation courses for practicing physicians. The most recent publication⁷ is entitled "Postgraduate Continuation Courses for Veteran and Civilian Physicians" and includes numerous courses especially designed for physician veterans. This listing is the longest ever published by the Council and represents a wide range of subject matter and a broad geographic distribution. This is the first list to be published to meet the needs of returning medical officers. It is hoped that by the end of this year many

90 per cent of them were in courses of about one month or less.² It is likely that a considerable increase in facilities will be required in courses of about three months' duration, especially in Internal Medicine (with 207 requests for training), Surgery and Subspecialties (134 requests), General Review (96), Obstetrics and Gynecology (88) and Pediatrics (88).

The statistics in table 4 indicate clearly that there must be an extensive organization of courses lasting from three to six months. Although in 1943-1944 only sixteen such courses were given to 118 physicians, there are 2,062 medical officers who will want work of this duration. The greatest numbers want training in Internal Medicine (518), Surgery (350), General Review (294) and Obstetrics and Gynecology (212). The greatest numbers of men who failed to specify the duration of their anticipated courses (totaling 1,641) also indicate an interest in further education in just these four fields.

Meeting this demand for courses of about three to six months' duration is primarily the responsibility of the medical schools, the medical school hospitals, insti-

more courses will have been organized especially for veterans, which can be included in the next published compilation of courses for veterans and other physicians scheduled for late December 1945 or early January 1946.

In planning review and refresher courses, the following should be borne in mind: (a) Refresher courses in the fields of Internal Medicine, Surgery, General Review, Obstetrics and Gynecology and Pediatrics are especially needed; (b) these should be courses of about three to six months' duration; (c) courses should be organized to start as soon as there is an enrolment of ten or fifteen, for example; (d) veterans should not have to wait unduly long to commence the work, so that programs permitting enrolment each month are desirable; and (e) plans should be based on the justifiable assumption that most of the medical school faculties now in service will be released by the time the peak demand for review and refresher courses is reached.

EXPANSION OF HOUSE OFFICERSHIPS

In collaboration with the Committee on Postwar Medical Service, the Council on Medical Education and Hospitals of the American Medical Association has circularized all the 1,054 civilian hospitals now approved for internships and residencies to ascertain the extent to which their facilities would warrant increases in numbers of residents in already approved residencies and the organization of new residencies in fields not now approved. The results to date, given in table 5, are most encouraging.

Replies from 292, or 28 per cent, of the hospitals indicate that they believe they can provide 2,382 additional residencies, which is 42 per cent of the estimated 5,727 additional residency positions required. Of these new residency places, over two thirds have already been surveyed by the Council staff and have been approved both by the Council and by the American board concerned. This means that there is already a large number of fully approved openings available for returning medical officers. Less than one third of

the places are in new residencies yet to be approved in hospitals already approved for internships and/or residencies in some other field. Surveys of the hospitals involved will be carried out well in advance of the peak of demobilization and the demand for residencies. See page 55 of this issue for further discussion.⁸

The statistics in table 5 would seem to indicate that, if all the residencies planned by the hospitals which have now reported are acceptable to the Council and the boards, the needs of the returning medical officers have already been practically provided for in Anesthesiology, Neurological Surgery, Pathology, Psychiatry and Neurology, and Radiology. This table also indicates that there is little doubt that the required facilities will probably be provided without too much difficulty in most other fields, if planning continues as earnestly as it has commenced.

At the residency level it would appear that provisions for training in Surgery will require further careful consideration, because of the large numbers involved. In this field it is especially important that the following devices be employed to increase the number of places available: (a) affiliation of approved hospitals with hospitals which, although not approved for

full residencies, seem able to provide some acceptable training, under the supervision of the approved hospital; (b) affiliation of hospital training programs with high grade board-certified surgeons in private practice, on a preceptor basis; (c) assignment of surgical residents to work in related fields in which the demand for additional house officerships will not be as great, such as Pathology and Radiology, and (d) assignment of residents to work in applied basic sciences.

In September 1945 the Council on Medical Education and Hospitals of the American Medical Association will publish its annual compilation of approved internships and residencies. This list will indicate the expanded number of places provided by those hospitals already approved for such training. This will be the first up-to-date listing of residency facilities for returning medical officers as well as other physicians.

ARMY AND NAVY EDUCATIONAL PROGRAMS

The armed forces have recognized the necessity for engaging in educational programs, especially for those younger officers whose assignments have necessarily been relatively nonprofessional or at least not such as would contribute materially to the officer's educational armamentarium in medicine. The need for such training is recognized by the Surgeons General, not only for the good of the officer himself but also because experience has amply demonstrated that medical care is improved in institutions and installations conducting educational programs. This applies to civilian and military hospitals alike.

The Navy and the Army Air Forces have concentrated primarily on hospital residencies. These have been and are being developed in close collaboration with the Council on Medical Education and the American boards. The aim is to organize residencies of sufficiently high caliber to diminish the load on civilian hospitals after the war. After inspection and consultation services by the Council, it is anticipated that numerous Air Force and Navy residencies will be added to the list of Council approved and Board acceptable residencies, to be published in revised form in September.

The Army is now engaged in organizing refresher and review courses of three months' duration. A further account of this program, as well as the house officerships of the Navy, appears elsewhere in this issue of THE JOURNAL.⁹

THE G. I. BILL OF RIGHTS

The educational benefits of the G. I. Bill of Rights (Public Law 346) as applied to physician veterans have been described in a previous publication.¹⁰ In summary, it may be said that (a) medical schools and hospitals are included as eligible for certification as educational institutions under this act, (b) approved hospitals are entitled to tuition benefits (\$500 per academic year of nine months) even if tuition has not customarily been charged in the past, provided the hospital can show that tuition is warranted on the basis of the costs of the educational program, (c) this tuition stipend may in turn be added to other stipends offered to the house officer if the hospital chooses, (d) the resident is eligible to receive his allowance under the G. I. bill, even if he is paid a stipend by the hospital, and (e) there will be a very liberal interpretation of the "interruption of training" provision of the law for men over 25 years of age.

8. Approved Internships and Residencies for Veteran and Civilian Physicians.

9. This issue, p. 37.

10. J. A. M. A. 126:709 (Nov. 11) 1944.

SUMMARY

1. Approved residencies in the specialties will have to be approximately doubled in number to meet the needs of physician veterans and new generations of medical graduates.

2. It is incumbent on hospitals and medical schools to effect this increase by expanding the places available in existing approved residencies, and by developing new residencies where the educational facilities seem to warrant it.

3. Hospitals approved for residencies should affiliate with such hospitals as seem capable of organizing some acceptable work under the direction of the approved institution, which might then rotate its residents through the affiliated hospital for a limited period of time.

4. To date, 28 per cent of the approved hospitals have indicated that they think they can provide 42 per cent of the increased number of residencies needed after the war. Two thirds of these places have already been approved by the Council on Medical Education and Hospitals of the American Medical Association.

5. The number of medical officers who state they will seek specialty board certification is over one half the number who have already been certified.

6. In addition to the continuation courses now available to physicians, there is a need for a considerable number of full time review and refresher courses of about three to six months' duration. Several medical schools have already organized such facilities.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

YEAST EXTRACT CONTAINING VITAMIN B COMPLEX (See New and Nonofficial Remedies, 1944, p. 606). The following dosage form has been accepted:

MCNEIL LABORATORIES, INC., PHILADELPHIA

• **Brewers' Yeast Tablets:** 0.32 Gm. Each tablet contains brewers' yeast 0.32 Gm., providing thiamine hydrochloride 0.167 mg. (55.5 U. S. P. units), riboflavin 0.023 mg. and niacin 0.195 mg.

Preparation.—

Dried Brewers' Yeast—U. S. P.—Granulated with a mixture of calcium carbonate, starch, sodium chloride, dried malt syrup, saccharin, vanillin, oil of chocolate and talc. The mixture is compressed into tablets.

PENICILLIN (See the Supplement to New and Nonofficial Remedies, 1944, p. 18).

The following dosage form has been accepted:

WILLIAM R. WARNER & CO., INC., NEW YORK

Penicillin Sodium: 100,000 Oxford Unit ampuls.

HEXESTROL (See THE JOURNAL, Dec. 9, 1944, p. 961).

The following additional dosage form has been accepted:

THE Wm. S. MERRELL COMPANY, CINCINNATI

Solution Hexestrol in Oil 5 mg. per cc.: 20 cc. ampuls. Preserved with 0.5 per cent chlorobutanol.

RIBOFLAVIN (See New and Nonofficial Remedies, 1944, p. 613).

The following dosage form has been accepted:

LAKESIDE LABORATORIES, MILWAUKEE

Tablets Riboflavin: 5 mg.

CONTRACEPTIVE DIAPHRAGMS (See New and Nonofficial Remedies, 1944, p. 340).

The following product has been accepted:

CONTRA CREME AND DIAPHRAGM CO., SEVERNA PARK, MD.
U. S. trademark 355,838.

Contra Diaphragm: Latex rubber diaphragm covering a spiral spring, the external diameter varying in gradations of 5 mm. from 50 to 95 mm.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report.

HOWARD A. CARTER, Secretary.

MAICO TYPE K VACUUM TUBE HEARING AID ACCEPTABLE

Manufacturer: Maico Company, Inc., 21 North Third Street, Minneapolis.

The Maico Type K is a three tube vacuum tube instrument consisting of a transmitter and amplifier case, a battery unit and an air or bone conduction reproducer.

Physical dimensions: Case: 4½ inches by 2½ inches by 1½ inches; 45 volt B battery: 3½ inches by 2 inches by 1½ inches; 1½ volt A battery: 3½ inches by 1½ inches (rod shaped).

Weight: Transmitter and amplifier case, 7 ounces; 45 volt B battery, 9 ounces; 1½ volt A battery, 4 ounces; total weight of instrument, 20 ounces.

Current consumption: A battery, 70 milliamperes at 1.5 volts; B battery, 1.7 milliamperes (with 1.5 volt A battery). The current drain is independent of the volume control setting.

Acoustical gain for speech: With large crystal receiver (1 inch diameter) and full volume, 45 decibels. This gain represents the average gain for three individuals, each of whom had losses of from 40 to 50 decibels for air conduction from 256 to 2,048 cycles. These individuals perceived speech through a high quality sound reproduction system at an average level of 45 decibels less intensity with the hearing aid than without it.

Acoustical gain for pure tones:

Frequency:	250	500	1,000	2,000	3,000	4,000	5,000
Full gain in decibels	29	32	45	56	47	33	17

These values were obtained with the large size crystal receiver, the tone controls being adjusted for maximum low and maximum high frequency response. The measurements were obtained with an artificial ear. The hearing aid was mounted on a body baffle.

Physical and mechanical features: The transmitter and amplifier case consists of a rectangular black plastic case of pleasing and more or less conventional design. A combined volume control and on-off switch, a round knurled molded plastic wheel, is conveniently located on the top of the case. The high frequency tone control adjustments are made by the insertion of small screws in the back of the instrument and the low compensation by the insertion of screws in the front of the chassis, accessible only by taking apart the case. The instrument has both high and low impedance output, enabling one model to be used with crystal or magnetic air conduction receivers or with high or low impedance bone conduction reproducer.

Performance: The instrument operates in an entirely satisfactory manner. There is a minimum of inherent amplifier, case and cord noise. The frequency compensation controls perform as represented.

Recommendations: The Council on Physical Medicine voted to include the Maico Type K Vacuum Hearing Aid in its list of accepted devices.

Maico Hearing Aid Type K.

EDUCATIONAL PLANS FOR RETURNING PHYSICIAN VETERANS

This series of articles presents concise descriptions of specific plans for meeting the educational needs of returning medical officers. It is hoped that these concrete programs will assist and perhaps guide other postwar planning groups such as medical schools, medical societies, specialty boards, foundations and other organizations, some of which may not yet have completed their plans for meeting this urgent need in medical education.

These brief articles on typical plans do not constitute a comprehensive coverage of the many definitive projects under way throughout the country. Such coverage is attempted elsewhere in this issue (see page 28) and more fully in other recent publications of the Council on Medical Education and Hospitals of the American Medical Association.¹

While the army and navy educational programs are for medical officers still on active duty, descriptions of them are included in this series because many of the officers benefiting from this work may soon return to civilian practice. Thus such programs for officers in service will supplement the projects of civilian institutions and organizations which seek to provide educational facilities for physician veterans.

THE PLAN IN NORTH CAROLINA

Wilburt C. Davison, M.D.
Dean, Duke University School of Medicine

All veterans, regardless of the age at which they entered the service and whether or not they had been in practice, are eligible under the G. I. Bill of Rights for a retraining course of one year at any institution approved by the Veterans Administration, which will pay fees to the institution up to \$500 per year and a subsistence allowance of \$50 monthly to the veteran; \$75 if he has a dependent. On completion of this one year course, veterans who entered the service under 25 years of age and those, regardless of age, who can show that their training was impeded or interrupted by their entrance into the service also are entitled to additional training of the same number of months they have been in the service. In other words, a medical officer who has been in the armed forces for thirty

months and entered the service at the age of 25 years or, regardless of age, had been an intern or resident but had not completed his resident training is eligible for three and one-half years of postwar training, i. e. one year plus thirty months.

Medical officers are of four groups: (a) former general practitioners, (b) ex-interns with nine to twelve months of training, (c) ex-residents with eighteen to thirty-six months of hospital experience and (d) former specialists. It is impossible to foretell accurately how many of the returning ex-interns and ex-residents will want exclusive training in the specialties, but it is hoped that many of them will decide to go into general practice, in which they are greatly needed. All but 15 per cent of patients can and should be handled by general practitioners, yet the results of the recent poll of the armed services indicated that more than 50 per cent of the medical officers intended to specialize on their return. Obviously there must be a variety of possibilities, which will provide whatever type of training the returning medical officer desires. The plan presented here will be followed by the medical schools of Duke and North Carolina universities, the Bowman Gray School of Medicine of Wake Forest College and the cooperating North Carolina hospitals.

1. Postgraduate Continuation Courses for Veteran and Civilian Physicians, J. A. M. A. 128: 751-761 (July 7) 1945.
Approved Residencies and Fellowships for Veteran and Civilian Physicians (to be published).
Lueth: Postgraduate Wishes of Medical Officers 127: 759-770 (March 31) 1945.
Johnson, Lueth and Arestad: Educational Facilities for Physician Veterans, this issue, p. 28.

Refresher or brush-up courses can be given at Duke and the Bowman Gray School of Medicine of Wake Forest College for the former practitioners by appointing additional instructors in medicine, pediatrics and obstetrics, at each of the two schools. It is realized that refresher courses are the least satisfactory method of postgraduate education. However, many of the medical officers who have been in practice may wish to return to their homes as quickly as possible to start rebuilding their incomes, so these refresher courses may have to be arranged in repeated short doses, emphasizing the recent medical advances, to accommodate the physicians who can spare only a week or two at a time.

The ex-interns and ex-residents, as well as some of the former general practitioners, may wish three to twenty-four months of hospital training in the specialties, and additional residencies will be provided. For example, the North Carolina teaching hospitals had six prewar approved pediatric residencies, but arrangements have been made with the pediatricians in the other hospitals for ten additional pediatric residents. Under this plan the hospitals can appoint sixteen residents instead of the usual six, each of whom would spend three to six months at one or more of these hospitals under the supervision of a licentiate of the American Board of Pediatrics, thereby obtaining a broader training than would be possible in one institution. A similar program has been planned in the other specialties and combinations of specialties. If the returning medical officers who have families prefer these residencies as externships, they will be arranged.

Hospital experience and tutoring for the former specialists can be easily arranged with the licentiates of the various specialty boards. The experience of working in a busy specialist's office should greatly help these returning officers to bring their knowledge up to date.

In addition, training will be provided at the three North Carolina medical schools in the basic medical sciences—*anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology*—for at least three reasons: first, the requirements of the specialty boards must be satisfied; secondly, the practitioner needs this training to help him improve his practice of medicine, and finally it is highly desirable to encourage some of the returning medical officers to become teachers in these subjects, in which they are greatly needed if good teaching and high research levels are to be maintained after the war.

All plans must be modifiable to accommodate for the wide range in the returning medical officers' prewar status, their variety of war experiences—*field or hospital duty*—and their rate of demobilization. For example, some of the ex-interns and ex-residents who return each year may elect to specialize in pediatrics and desire one or more years of pediatric residency, while others may want to become general practitioners and need only refresher courses in pediatrics, obstetrics and medicine. This plan is flexible enough to fit these various needs and can be started tomorrow morning or at any time a medical officer returns. Further information can be obtained by writing to the deans of the University of North Carolina School of Medicine, Chapel Hill, N. C., of the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., and of Duke University School of Medicine, Durham, N. C., or to the Postwar Planning Committee of the Medical Society of the State of North Carolina, Box 3701, Durham, N. C.

REVIEW AND REFRESHER COURSES

Ovid O. Meyer, M.D.

Professor of Medicine, University of Wisconsin Medical School

The University of Wisconsin Medical School has four plans for meeting the desires and needs of physicians returning from military service. Particular emphasis is to be placed on a review and refresher course of twelve weeks' duration. This course is planned especially for returning general practitioners and has the purpose of review and study of the recent advances in the major fields of medicine. Four weeks will be devoted to medicine (including a week of neuropsychiatry), four weeks to general surgery and allied specialties, two weeks to pediatrics and two weeks to obstetrics and gynecology.

This course will consist of ward rounds, instruction in basic sciences with clinical application, clinics, lectures, conferences and round table discussions. Instruction hours will be from 8 a. m. to 12 noon and from 2 to 5 p. m. daily (Saturday afternoons excluded). This course will be limited to twenty, with a minimum of ten. The first session will be offered when ten enrollees are registered with the dean of the Medical School and the course will be repeated each three months while the demand exists. The instructors in this course will be those of professorial rank on the full time or part time staff of the Medical School. The practical will be emphasized.

The course for medicine (after rounds from 8 to 11 each morning) will include three weeks covering advances in laboratory medicine and clinical biochemistry, cardiovascular physiology, allergic diseases, malaria, chemotherapy, nutrition, common skin diseases and proctoscopy. Extended discussions and clinics covering the blood dyscrasias and hemorrhagic diseases, diseases of the gastrointestinal tract and jaundice, renal diseases, tuberculosis, hypertension, cardiovascular diseases and endocrine dysfunctions will be a part of the course.

The subjects to be covered in the week of medicine devoted to neuropsychiatry are the neurologic examination, neuroanatomy, cerebral apoplexy, subarachnoid hemorrhage, traumatic lesions, polyneuritis, basal ganglions, central nervous system tumors, central nervous system syphilis, diagnostic procedures, discussions on the psychiatric patient, the diagnosis and therapy of the psychoses, and the psychoneuroses.

The two weeks in pediatrics will be allotted for study of care of the premature infant, chemotherapy in children, rheumatic infection and its prevention, pediatric dermatology, treatment of hemangioma in infancy, technique of intravenous and bone marrow transfusions, infant feeding, diarrheas, pancreatic diseases, congenital defects, diseases of the newborn and respiratory diseases, congenital heart disease, hypertension, convulsions, intestinal parasites, management of megacolon, meningitis, communicable diseases, disturbances in growth, nutritional deficiencies and urologic conditions in childhood.

The surgical work of four weeks will emphasize surgical anatomy and the techniques of special examinations, as in orthopedics and neurosurgery, for example. In addition the following subjects will be covered: anesthesia, the optic fundus, acquired and congenital anomalies, chemosurgery, the treatment of traumatic wounds, varicose veins, genitourinary infections, gallbladder and liver disease, burns, hernia, prostatic disease, diseases of the breast, appendicitis, empyema,

urologic neoplasms, peptic ulcer, gastric carcinoma and surgical pulmonary, esophageal and rectal diseases.

Two weeks will be assigned to obstetrics and gynecology, during which time the following subjects will be covered: pelvimetry, vomiting of pregnancy, abortion and premature labor, pain relief in labor, obstetric hemorrhages, normal pregnancy, minor complications of pregnancy, toxemias, normal labor, complications of the newborn, sterility, methods of gynecologic examination, leukorrhea, diseases of the cervix and of the uterus, management of the normal puerperium, puerperal infections and complications of the menopause, cesarean section, treatment of cancer of the female genital tract, diseases of the tubes and ovaries, female endocrinology, backache, radiation therapy in gynecology, and uterine malpositions. Three afternoons will be devoted to manikin demonstrations.

In addition to these review and refresher courses, the University of Wisconsin offers training for physicians in three other categories, as follows:

1. For those who wish to acquire specialty training for certification, three year residencies in all of the specialties will be available. It is planned to increase the number of residencies from a prewar number of approximately forty to about sixty.

2. A two to six months course for specialists will be available. Attendance will be open only to those who have had training in their specialty. It is designed as a review and refresher course for specialists. This course will emphasize preclinical as well as clinical aspects of each specialty and recent advances of the respective fields. The training will be both theoretical and practical and will be available in the departments of internal medicine, neuropsychiatry, surgery, obstetrics and gynecology, pediatrics, urology, orthopedics, otorhinolaryngology, ophthalmology, dermatology and physical medicine.

3. The preclinical departments are open to properly qualified men and women who wish to work for one year or more on any project in which they are interested.

SURVEY OF FACILITIES FOR TRAINING IN A SPECIALTY

Ralph K. Ghormley, M.D.

Chairman, Joint Committee of the American Orthopaedic Association
and the American Academy of Orthopaedic Surgeons

The American Board of Orthopaedic Surgery has recognized for some time the need for institutions which could furnish training to discharged medical officers who have not been able to complete the requirements for examination by the board and for those who may wish to repeat any phase of training in orthopedic surgery. The secretary of the board, Dr. Guy Caldwell, pointed out this need months ago and, as chairman of the Section on Orthopedic Surgery of the American Medical Association, he has emphasized the need for more facilities for the training of orthopedic surgeons.¹

The executive committees of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons, also realizing the importance of furnishing the necessary facilities for training such as has been mentioned, appointed a joint committee to plan for this important work. This committee has cooperated closely with the American Board of Orthopaedic Surgery. It seemed to the members of

the board, as well as to the executive committees of both organizations, that the task would be best accomplished by such a joint committee rather than to leave it entirely to the board.

The joint committee studied the problem before it with two things in mind. First, adequate orthopedic training is now composed of three branches: adult orthopedic surgery, children's orthopedic surgery and the surgery of fractures and trauma. None of the surveys available seemed to show the true picture as to the number of institutions available for training in those branches. Second, the reports on Lieut. Col. Harold C. Lueth's surveys² were studied and the number of additional residencies probably needed was noted.

The conclusions of the joint committee were that its first task was to survey the facilities which could be used for training orthopedic surgeons. This survey must be on a nationwide scale.

It was found that partial surveys had been made in some areas by various orthopedic surgeons for local societies. Using these individuals as far as possible, and appointing other orthopedic surgeons familiar with conditions in their communities, the entire nation was divided into districts and each district was assigned to an orthopedic surgeon who the committee felt should be able to furnish the desired information. These men were asked to furnish the joint committee with the names of hospitals where orthopedic facilities were available, the number of beds available for each of the three divisions of orthopedic training, the number of residencies now available and the number of residencies contemplated in the postwar period.

In many instances the surveyors made personal visits to the centers on which they reported, thus getting first hand information and being able to offer suggestions to those concerned. The questionnaires used were made as simple as possible because the members of the joint committee felt that a large mass of needless information was often confusing, whereas the accurate recording of a minimal number of pertinent facts would constitute a much more workable survey. In some instances additional information was furnished, such as the number of hospital admissions, lists of the types of cases treated and operations done. These too were reviewed by the joint committee.

It was pointed out by the joint committee that the inclusion of an institution in the survey did not accredit that institution for training orthopedic surgeons. Accrediting must be by the Council on Medical Education and Hospitals of the American Medical Association, and approval must be by the Committee on Hospitals of the American Board of Orthopaedic Surgery.

From the reports of the various surveyors, the facts have been tabulated. The joint committee has reviewed all the results of the survey and has noted the following facts. First, because of the war, with the shortage of personnel and restriction of the number of residencies, many services are not as well staffed as in peacetime. Many of these services would welcome men from the armed services at once to augment their resident staffs. Second, a good many services are organized with adequate facilities and personnel to furnish good training for orthopedic surgeons but have not been accredited by the Council on Medical Education and Hospitals for such training. Many of these will be surveyed by the Council and accepted by the board, thus augmenting the

number of services available for training. Third, many facilities have adequate personnel and material but are not organized for training orthopedic surgeons. In most instances, officials of these institutions have expressed a desire and willingness to organize themselves for such work. The members of the joint committee feel that their main duty from now on is to help such units complete their organization in order to furnish training for orthopedic surgeons.

One of the problems the joint committee is considering is the proper placement of men in institutions to complete their training. Just which phase of orthopedic training each individual will need is not now apparent to the joint committee. It is hoped that the joint committee will be able to determine this in each instance or, at least, in a general way. If needs of individuals can be determined, a more definite plan for supplemental postwar training can be worked out in each case than otherwise would be possible.

The joint committee feels its responsibility to the men returning to civil practice from the armed services. It is fully aware, however, of the fact that much harm can be done by encouraging the use of institutions where personnel or material is inadequate. The standard of training must be kept up to a high level; otherwise the very purpose for which all are striving will be defeated. It is hoped that the efforts made will lead to a workable plan, whereby every man who leaves the service may be able to fulfil his program of training and return to civil practice with a well rounded and adequate program of instruction.

THE CONTRIBUTION OF A FOUNDATION

Robert S. Morison, M.D.

Assistant Director, Medical Sciences, the Rockefeller Foundation

In setting up its plan for aiding in the postservice education of returning medical officers, the Rockefeller Foundation sought to help reestablish the flow of men trained as teachers and investigators in the various branches of medicine. The normally very long training of such men ceased abruptly at the onset of war, and it seemed likely that the country would suffer a deficit in the supply of teachers, a deficit equal to a normal five to ten year output. Estimates of the further deficit in the number of "second generation" students whose training would suffer from a lack of competent young teachers cannot be accurate. The situation promised to be sufficiently grave, however, to justify a particular concern for prompt expansion in the training of such personnel as soon as decreasing military requirements allowed. It was also hoped that, if a plan could be set up in working order early in the emergency, it might demonstrate the possibilities and pitfalls likely to be encountered when large scale efforts become necessary later on.

In devising a scheme to meet these obvious needs, two principles appeared to be fundamental: flexibility and rapidity of action. The postwar needs, desires and capabilities of medical officers do not fall into a few simple categories susceptible of manipulation by rigid rules. The services in which they wish to receive further training differ in organization, numbers of patients, kinds and amounts of equipment, types of problems investigated and academic tradition. Thus, if advanced training is to be a success, the diverse characteristics of the man seeking training must be

fitted to the opportunities and needs of the service in which he wishes to work. Careful individual consideration of returning medical officers is especially necessary because these men are as a rule further advanced on the nonprofessional side of their life than they are in medicine. In many instances they have acquired family responsibilities and a standard of living more appropriate to a man well established in practice or an investigative career. The peculiar demands of military life have developed their personalities and attitudes far beyond those usual in a resident hospital staff. Yet their formal medical training may have consisted only of a scanty nine months internship.

This process of adapting the opportunity to the man must be done quickly. Not only the officers but the hospitals and medical schools are impatient to set to work repairing the holes torn in medical education by the war. Another more personal consideration counseled the wisdom of promptness. It was felt that many men isolated in the outposts of a world at war might be stabilized and encouraged by early assurance that definite, well planned opportunities await their return.

In order to ensure speed and flexibility the foundation decided to leave the selection of men and the planning of individual programs entirely to the heads of the various departments to which funds have been allocated. When possible the department head has submitted a sketch of his plans to the foundation so that it may judge whether it falls within the very broad limits set up by the trustees. A record is also being kept of the names and qualifications of the men appointed. Aside from these very general requirements, the department heads have been free to expend the funds as seems best to them. The sums allocated to the various medical school departments participating in the program have varied between \$4,000 and \$8,000. In a few cases the entire sum will be devoted to providing a single relatively advanced man with an appointment of two or three years' duration. In others, small amounts will be given to several men as a supplement to income derived under the G. I. Bill of Rights. The duties and opportunities of the various positions will also vary from those of the familiar senior internship to the relatively advanced responsibilities of a junior member of the regular teaching and research staff. Several of the programs include study in the basic sciences related to the clinical specialties in which the assistantships are held.

One further technical point is worth mentioning: The holders of these appointments will have titles conferred by the participating institutions and appropriate to the particular individuals concerned. They are not to be known as Rockefeller fellows, and no negotiations with candidates are carried out by foundation officers. Announcement of appointments, as indeed are all other technical details, is left to the participating departments.

No effort even approaching the magnitude of the necessity could be made by a single individual or foundation. The total funds allocated by the Rockefeller Foundation now stand at \$500,000. These have been divided between 65 departments in 26 schools. As this is written 34 appointments have already been made, in spite of the difficulty of arranging many of the details so far in advance of the date of expected demobilization. Unquestionably there is an enormous demand for the sort of training contemplated by the program. The foundation is therefore only too acutely aware of the inadequacy of its support, which can at best provide 250 men with a training appointment of one year.

NAVY RESIDENCIES

Rear Admiral W. J. C. Agnew (MC)

Assistant Chief, Bureau of Medicine and Surgery, United States Navy

This subject has been proposed to the Bureau of Medicine and Surgery of the United States Navy for presentation in the symposium on postwar educational rehabilitation of medical officers. It is true that the establishment of a definite program for residency-type training in the specialties in naval hospitals has had such rehabilitation as one of its objectives, but the full scope of the program includes much more than this one phase of graduate medical education.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION¹ recently afforded the Surgeon General the opportunity to outline in considerable detail the program of the Medical Corps of the Navy for internships and residency-type training. The latter was merely a logical outgrowth of the former, internships in naval hospitals having existed with formal Council approval for approximately twenty years.

The purposes in instituting a concrete plan for more advanced medical training in naval hospitals generally and uniformly throughout this country, to be based on the best of civilian standards, were outlined in the paper referred to. As stated, "This interest in the development of an educational program was . . . primarily and fundamentally because we are concerned with . . . improvement and betterment in standards of medical care of our patients. It has been entirely incidental to this that better than average opportunities for internship and residency-type training are thus provided for our medical officers."

The design of the plan was to establish by general order to medical officers in command of United States naval hospitals certain fixed, fundamental standards covering supervised study and treatment of patients, formal clinical rounds, departmental and general staff conferences, and the maintenance of excellent libraries and other educational and training facilities. Simultaneous requests were made to the Council on Medical Education and Hospitals of the American Medical Association, the American boards and the American College of Surgeons for survey and approval of these facilities for residency-type training precisely as is done by these organizations in civilian hospitals. The American College of Physicians also exercises jurisdiction, but indirectly, in such affairs.

Quite frankly, our interest in providing training in the specialties for the officers of the Medical Corps while still on duty is greater than that for the so-called rehabilitation, especially by short courses, for officers after their discharge from service, although all of these proposals undoubtedly have merit. Equally frankly, we are pleased to take advantage of the fact that there are many outstanding clinicians and teachers now serving in the reserve Medical Corps, and it is fully recognized that this has offered an unparalleled opportunity to initiate this advanced teaching program with their help, especially for the benefit of the "regulars" who must later carry it on. We are also greatly interested in the progress of our reserve officers, who cannot fail to profit from our program pending their return to civilian residencies or practice. Thus the Navy residency program may be viewed as anticipating and lessening the expected demand from naval officers for

postwar training by supplying this in so many instances prior to release from active duty.

There has been some misunderstanding of our program. For example, specialty services in naval hospitals are not termed residencies, and junior medical officers assigned to such duties are not to be known as residents. The training while on duty is of the residency type and conforms to these standards, so that junior ward officers on duty in formally approved services may have time so spent accredited to them before the American boards and the American colleges. Opportunities for such assignments are limited in number, and war needs for young medical officers are still pressing.

On nearing completion of a tour of sea duty, and rotation back to the United States, a medical officer may make request to the Bureau of Medicine and Surgery, through his commanding officer, for assignment in a specialty in a naval hospital. Each such request is given close consideration by a board sitting for this purpose. If a young officer's request is justified by some substantial degree of previous special residency training or proved ability so that he can be used to the direct advantage of the patients and is thus already primed to absorb such training, he is likely to find himself so assigned as vacancies occur. Older officers, especially those fully qualified in a specialty and certified by their boards, are finding themselves appropriately assigned, more and more, for work and for teaching in their specialties. This is, obviously, to the advantage of the patients, and these officers are likewise extremely important in this educational program.

Again quite frankly, we cannot undertake during wartime to begin advanced training in a specialty for officers who have had no such training except in limited numbers of instances. Nevertheless it is important that intensive training be afforded especially to young officers of the regular Medical Corps, who will become the leaders and "key men" later in conducting the medical services of naval hospitals in the long postwar period for which provision must definitely be made. It is suggested, incidentally, that these men should profitably have only part of their residency-type training in naval hospitals, with the idea that later when we are no longer at war arrangements may be made by the Navy through affiliations for the remainder of their residency training to be obtained in civilian medical centers.

These points about residency-type training in naval hospitals have been outlined for two purposes. One of these is to show that its full scope is not limited to this one feature of rehabilitation of medical officers returning to civilian practice.

The other purpose is to reiterate and to reemphasize that it is, nevertheless, a distinct contribution to any such program. Many reserve officers are being provided with outstanding opportunities to resume their interrupted careers in training for a specialty, even while still in naval service; others, fully qualified as specialists, are finding "rehabilitation" and at the same time making important contributions to the Medical Corps, both to our younger medical officers and to our patients, while still on duty.

There seems to be one critical comment worth making on the educational plans for returning physician veterans. This is that the program has been consistently and almost exclusively directed toward veterans returning to civilian life.

1. McIntire, Ross T.: Internships and Residency-Type Training in United States Naval Hospitals, *J. A. M. A.* 128:264 (May 26) 1945.

Long after the end of this war it will be necessary to maintain a large standing army and navy with their medical officers. There is no good reason why these short "refresher" courses, or longer and more highly specialized courses, partial or complete residencies, and other educational plans for returning veterans should not also be available to and freely utilized by the officers remaining in regular service. In fact, our naval hospital residencies are not expected, in many instances, to offer a complete residency training; it is hoped and planned in the future to have our officers develop themselves further through broadening civilian contacts, and these proposed courses and residency facilities now being planned in such profusion should, properly, be open to men still in military service as well as to those returning home to practice civilian medicine.

Our point of view of the postwar medical educational problem envisions this "refresher" or rehabilitation plan developing into a permanent program of broad scope open to veterans in the reserve corps and to medical officers in the regular corps of the Army and Navy alike. We expect that our residency training program will lead to qualification of officers of the regular Medical Corps of the Navy for certification by the boards and fellowship in the colleges and will likewise qualify them for membership and fellowship in the various national special societies. The Medical Corps of the Navy recognizes fully the advantages that have come from the drawing in of reserve officers from civilian life, and it does not wish to lose these contacts.

In other words, everything possible should be sought to develop all officers of the Medical Corps of the Navy and to effect a closer liaison in peacetime between military and civilian medical practice and practitioners than may have existed heretofore.

It is my belief also that our ambition to provide such opportunities for advanced medical training both in and out of the specialties with development of personal attainments and national recognition offers a great inducement for medical officers, now serving for patriotic reasons, to make a permanent career of naval service.

ARMY REFRESHER COURSES

Lieutenant Colonel Harold C. Lueth, M. C., A. U. S.
Office of the Surgeon General

The Army has taken definite steps for assisting medical officers in getting refresher work in hospital training while they are still in the military service. Early this year steps were taken so that officers assigned to field, tactical and administrative positions would be given an opportunity to get a twelve week refresher course in one of the large named general hospitals in this country. Before the defeat of Germany all medical officers who returned from overseas assignments had the chance to apply for such training. At present many officers returning from overseas are applying for refresher training. A postcard application Form WD AGO 8-94 filled out at reception stations made it possible for returnees except those in redeployed units to apply almost as soon as they arrived in the United States.

Assignment to refresher courses has been limited to officers who volunteered for this work and who were previously assigned to command, administrative or semiprofessional positions for one year or more. Applications are received and processed by the Personnel Service, Office of the Surgeon General. Preference was given to officers who returned from overseas,

though those serving in the continental United States were not excluded. It is the present policy to assign not more than six officers to any one service, and no hospital will have more than twelve students at any one time. During the last four months more than 170 officers have been assigned to refresher courses.

Refresher training courses were in several main fields, as medicine, surgery and laboratory work. Courses in medicine and surgery followed broad schedules that had been developed in the Training Division of the Office of the Surgeon General. For example, at Tilton General Hospital special schedules have been evolved to fit the needs of the students and the available teaching material. They included two hours of actual contact and work with the patient. Ward work at which a complete history is obtained and a careful physical examination is made constitutes a specimen of the type of instruction in internal medicine. Courses in surgery include careful attention to operating room procedures and to preoperative and postoperative care. Administration of fluids and the treatment of shock, control of pain, treatment of fractures and use of penicillin, sulfonamides and other means of modern therapy are some of the main subjects taught. In medicine emphasis is placed on new diagnostic procedures, treatment of tropical diseases and other recent advances in treatment. Student officers in medicine are rotated between the section of general medicine, cardiology, gastroenterology, neuropsychiatry, allergy, communicable diseases and dermatology. Surgical refresher courses included the allied specialties of orthopedic, genitourinary and septic surgery and when available anesthesia, eye, ear, nose and throat, neurologic and thoracic surgery. An hour clinical conference is usually held in the morning before lunch, during which some special subject is discussed in detail by a chief of service, section or branch. In the afternoon an opportunity is given men to follow the chiefs of services in their ward rounds. An applicatory or on the job method of training is afforded to all students. Some hospitals have special x-ray conferences, clinical pathology and the other staff meetings. All schedules have a clinical pathologic conference at least once a week. Attendance at boards to determine the disposition of patients either for retirement, discharge for medical reasons or return to duty is optional and not a required part of the training. The abundance of clinical material in the large general hospitals, the presence of a qualified professional staff, who serve as instructors, and the availability of medical libraries make such courses very desirable educational methods of instruction.

Similar courses in laboratory work are offered to laboratory officers who have been assigned for the past year or more to administrative or command duties. The resources of Service Command laboratories are utilized and men are given an opportunity to study all phases of laboratory procedure, including bacteriology, parasitology, biochemistry and clinical pathology.

Considerable time and thought have been given the matter of refresher training to medical officers in Europe. Basic medical and surgical refresher training is being given in a number of cities in Europe. Medical officers awaiting transportation to the United States may apply for these courses. It has been reported that more than eight hundred officers are currently enrolled in the basic courses of medicine and surgery. Advanced courses of instruction are open to fewer but more highly trained medical officers. There are courses in anesthesiology, radiology, physical therapy, cardiology and

ophthalmology. Applicants must have completed at least one year or more of training after completing their internship in the special field in which further instruction is desired. Medical officers assigned to general hospitals as ward officers in these fields, on request, may be given intensive training for two months. Training of this type probably will be acceptable to the American specialty boards as a partial fulfillment of some of their requirements. With these restrictions it is evident that two month courses are not designed to produce qualified specialists, but they should be recognized as a supplementary method of training.

In a number of island bases there have been established basic medical courses designed to help the general practitioner. They include instruction in new methods of diagnosis, treatment, laboratory procedures and some work in anesthesiology, radiology and physical medicine. In the Army many of the special features of medical practice are referred to specialists, whereas in civilian general practice the doctor himself frequently is required to assume some of this work himself. This is especially true for laboratory work, anesthesiology and eye, ear, nose and throat work. General practitioners will benefit most from these courses.

Medical and surgical consultants of the European Theater have been most helpful in selecting qualified teachers to give both the basic and the advanced courses of instruction. Courses are well attended, give excellent training and are enthusiastically accepted by the student officers. In Paris, Edinburgh, Glasgow, London and Oxford, existing medical schools and civilian faculties have been utilized to help give these courses.

At the named general hospitals in the United States the chiefs of medicine and surgery are largely responsible for the instructional work. In some service commands the consultants are called on to give an occasional lecture or clinical demonstration. The facilities of the Wartime Graduate Medical Meetings are also useful in supplementary instructional work at the general hospitals. Excellent clinical pathologic conferences have been arranged at several general hospitals. Medical officers have been very enthusiastic about this type of refresher training and have expressed great satisfaction in being allowed to get such work. Through these means it is believed that the Army is doing much toward assisting medical officers in regaining whatever professional skills they might have lost as a result of pure military assignments.

FORTY-FIFTH ANNUAL REPORT ON MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

Victor Johnson, Ph.D., M.D.

Secretary, Council on Medical Education and Hospitals of the American Medical Association

In this forty-fifth annual compilation of information and statistics on medical education in the United States and Canada are included discussions of the military programs in medical schools, the supply of incoming medical students and the changing status of the accelerated program.

In addition there are included the calendars of the medical schools and data on enrolments, graduates, pre-medical education, licensure, internships, fees, continuation courses and specialty boards. Medical schools are described and recent educational developments discussed.

The Educational Number of THE JOURNAL provides essential material of great value to military and government agencies, medical schools, physicians, medical educators, hospital officials, students, interns, residents and those concerned with specialty certification and graduate and postgraduate medical education.

In the wartime days of multiple demands on every one's time and energy, it has been particularly gratifying to the Council and to THE JOURNAL to receive the wholehearted cooperation of all concerned with supplying the information compiled in this Educational Number. Military and government officials and officers of medical schools and other institutions have faithfully provided the Council not only with the material in this issue but with many other records throughout the year. They have generously assisted the Council staff in its inspections and surveys. For these services, sincere thanks are due not only from the Council and THE JOURNAL but also from every one who finds this publication useful.

THE SUPPLY OF MEDICAL STUDENTS

With the cessation of hostilities and the probable discontinuation of induction into the armed forces in the near future, every effort must be directed toward a resumption of the training of qualified premedical stu-

dents in adequate numbers. During the past year there have been virtually no able bodied male students in this field. Even after demobilization is complete, we shall probably need about 30,000 more physicians than before the war, primarily because of the requirements of the Veterans Administration (about 15,000) but also because of the needs of the peacetime Navy (about 5,000) and the Army plus possibly a compulsory universal military training program (about 10,000). This estimate disregards extra physicians required to provide replacements for casualties among medical officers, medical assistance to liberated countries and the more complete and extensive medical care demanded in this country.

Even if admissions, enrolments and graduations from our medical schools should continue at the present levels, only about half of this need would be met, since 40,000 students enrolling would receive the M.D. degree in the period 1942 to 1948 and 24,000 physicians will have died during that time. Thus, under the most favorable conditions only about 16,000 additional physicians will be available after the war to do the work of 30,000.

From now until at least 1947, medical school freshmen must be women, or men who were physically disqualified, under or over the draft age or veterans. Because people in these categories are limited in numbers, those admitted to our medical schools in the next year or two will be appreciably reduced in numbers or in quality.

The termination of the war earlier than every one anticipated was more than fortunate for numerous reasons; yet considerable damage has already resulted in medical education. There will probably be a lag for the better part of a year before the numbers and quality of men in premedical studies will reach the prewar levels.

MEDICAL SCHOOL CALENDARS

Before the war practically all medical schools admitted a freshman class each fall and graduated a class each spring, with one academic session per calendar year. Educational data could be presented annually without confusion arising as to which class was being discussed. This regularity is no longer the case. Schools commenced the accelerated program at different times, and

Therefore it is necessary to identify which session is being described in this Educational Number and relate it to sessions described in preceding Educational Numbers. In the 1943 Educational Number most of the data presented applied to the "session preceding the first class entering in 1943." Most of the information presented in 1944 applied to the succeeding session, "the first session commencing in 1943."

TABLE 1.—Admission and Graduation Calendars of Medical Schools in the United States

other local conditions varied so that admission and graduation dates are distributed throughout the year, as shown in tables 1, 2 and 3. Even within a given school the various classes (freshman to senior) may have different dates for the beginning and ending of the academic year; this will become increasingly true as more schools return to annual admissions while still accelerating.

Most of the material presented in the current issue applies to that session which for most schools began in September or October of 1944 and terminated in June 1945. This session will henceforth be referred to as the 1944-1945 session, even though this academic year commenced early in 1945 in a few schools. Since the publication of the 1944 Educational Number and up to June 30, 1945 all medical schools have had two gradu-

ating classes, except ten schools (Arkansas, Howard, Illinois, Tulane, Michigan, Woman's Medical, Meharry, Southwestern, Baylor and Marquette) in the United States and all but four (Manitoba, McGill, Montreal and Laval) in Canada. The opening and graduation dates which identify the sessions for which data are presented in the current issue are given for each school in tables 1, 2 and 3.

These tables also present the dates of the next two entering freshman classes as well as the next two graduation dates, except in a few instances in which schools give the date for one graduating class. The admission dates given indicate that a return to annual admissions henceforth is now planned in all medical and basic science schools in the United States except for six schools (Louisville, Wayne, Minnesota, Meharry, Vermont and Virginia) still planning to continue the

graduate students next in March 1946, although there will be graduates every month except November 1945 in this twelve month period. This table will be particularly valuable to internship hospitals by giving the numbers of graduates from the various schools and the times they will become available for internships. These figures are recapitulated in table 5, which also shows the number of schools admitting new freshman classes during each month of the ensuing twelve months.

By June 30, 1945 all medical schools in the United States except ten and all but four in Canada had completed a cycle of four graduating classes in three calendar years. During these three years, to June 30, 1945 there have been 20,662 graduates in the United States. By comparison there were 15,535 graduates in the three immediately preceding prewar years to June 30, 1942. This represents the graduation of an extra 5,127 stu-

more frequent admissions and seven schools (California, Southern California, Hahnemann, Jefferson, Colorado, Utah and Dartmouth) which have not yet determined their calendars. It is probable that some of these institutions will decide to return to annual admissions before the 1946 class enters. Tennessee will continue to admit students quarterly.

All Canadian schools have returned to annual admissions.

THE ACCELERATED PROGRAM

Even though admissions are annual, acceleration will be continued for upper classes containing military student personnel, at least for the present. Therefore graduations will occur every nine months as long as acceleration continues in upper classes which entered school at nine month intervals. All Canadian schools have commenced to decelerate, and in some of them this adjustment has been completed for all classes.

The distribution of graduates throughout the next year is given by schools in table 4. Most schools will

dents in the past three years. This contribution of medical schools to the successful prosecution of the war is immeasurable, coming at a time when faculties were depleted in numbers and the demands on the time and energy of those remaining were excessive. Five thousand extra physicians can provide medical care for 100,000 hospitalized veterans, 1,000,000 soldiers or sailors or 4,000,000 civilians. However, the recent policies of the national authorities pertaining to pre-medical students will more than offset this net gain in the next few years.

During the past three years there has been a fairly general agreement that the accelerated program conducted during that time has been educationally undesirable. However, it is important to remember that factors other than acceleration itself have operated to the detriment of the medical educational program. Important among these have been the necessity for continuous teaching by most instructors, and the shortage of instructors.

These two difficulties will now be partially corrected. With annual admissions, even though acceleration is continued, the teaching load of the staff is reduced. If a school is on the quarter system accelerating and admitting a new class every October there will be no freshmen in school during the summer quarter, no sophomores in the spring, no juniors in the winter and no seniors in the autumn. It follows that a faculty

factors which have operated in our medical school programs. An uncritical urge to return to the "good old days" of the traditional calendar should be avoided. Certainly medical schools should oppose the peacetime compulsions by law or licensure regulations preventing even the most competent students from completing their work in three years, by requiring a specified time to elapse before completion of the medical work.

member who teaches only freshmen will have no teaching duties in the summer. One who teaches only sophomores will be free from teaching in the spring, and so on. In addition, the prospects seem good for the return from military duty of a significant number of key teachers in the next few months.

It would be highly desirable to continue the experiment of medical school acceleration under these somewhat more favorable conditions. In attempting to assess the educational desirability of some acceleration it is necessary to evaluate independently the various

It seems probable that some schools will continue the accelerated program in modified form with annual vacation periods somewhat intermediate between the too long peacetime three to four months and the too short wartime intermissions.

It appears that all the licensure difficulties introduced by the accelerated program have been appropriately adjusted, at least so far as the work in the medical school itself is concerned, for the duration of the emergency. Unfortunately, some of the states have indicated an immediate return to prewar regulations when the

emergency is over. In some instances this will mean that even the most highly qualified students will be prevented by law from completing their medical studies in less than a stipulated minimum number of months. Whether or not some degree of acceleration is educationally desirable, no state law should require every

student to take an annual vacation of sharply defined duration.

The relationship of licensure to the "acceleration" of the 9-9-9 internship and residency program is further discussed on page 52.

THE MILITARY AND CIVILIAN STATUS OF MEDICAL STUDENTS

The military status of medical students in the United States is shown, by schools, in table 6. Nearly 80 per cent of all medical students are in the Army or Navy programs. The distribution of students in military and civilian categories by classes is shown in table 7 and in the chart. There has been a decided change in the composition of medical classes in the years since the

Percentage distribution of students in military and civilian categories by classes, 1944-1945.

military programs commenced in our medical schools. In the senior and junior 1944-1945 classes over 90 per cent of the students are in Army or Navy programs. In the sophomore class this percentage just exceeds 80. The freshman class shows a sharp decrease in military students. Over half of them are in a civilian

status. In this class there are 5.3 per cent of physically disqualified males, 7.2 per cent of women, 8.6 per cent of veterans and 26.2 per cent of occupationally deferred men. This large number of deferred men resulted from a special but temporary concession of the Selective Service System. Army students now in A. S. T. premedical work will be available for one class in 1945 in each medical school, and Navy V-12 men will also be assigned to 1945 entering classes. However, the medical schools estimate a reduction in the 1945-1946 entering freshman class. In 1946 medical schools must obtain their students from sources which supplied only about one fourth of the 1944-1945 freshmen. One of two consequences is inevitable: There will be too few applicants to provide a full freshman class or some schools will admit inferior applicants.

There already is evidence of the latter. Certain schools have already admitted some men with very questionable qualifications for the study and practice of medicine. Despite a postwar need for more physicians than were required before the war, the admission of incompetent men or women to our schools cannot be tolerated, since these people will be the doctors of tomorrow. The Council on Medical Education and Hospitals of the American Medical Association will be especially concerned with the quality of freshmen admitted to our schools in the next few years.

PREMEDICAL EDUCATION

The premedical curriculums of the Army Specialized Training and the Navy V-12 programs are acceptable to all schools holding contracts for Army and Navy medical students. These programs also meet the minimum admission requirements formulated by the Council on Medical Education and Hospitals of the American Medical Association and by those states whose licensure laws include specific premedical requirements.

For civilian applicants, most schools state their 1946 admission requirements in academic years or semester hours. In tables 8 and 9 (pages 46, 47 and 48) these are given for each medical and basic science school in the United States and Canada. The trend toward the former prewar requirements continues. Compared with thirty-nine schools in 1945, there are fifty-six schools requiring more than two years of college preparation for students entering in 1946. There are three schools (two Canadian) requiring a degree or four years of college, fifty-three schools requiring about three years, and thirty asking about two years. One Canadian school admits students after one year of premedical work.

The American Council on Education has received a grant of \$150,000 from the Carnegie Corporation of New York and the General Education Board for the study of various wartime accelerated and other special educational programs to determine whether certain features of such plans appear to warrant permanent inclusion in our educational armamentarium. It is hoped that the premedical A. S. T. and Navy V-12 programs will be included in this study. It would be particularly important to know the relative performance in the first year of medical school by these military students as compared with those who took their premedical work in nonaccelerated programs either during or prior to the war. There seems to be a general impression among medical school faculties that students entering now are inferior to those entering before the war, but there are few objective data and the results of premedical acceleration are not clearly differentiated from

those of the medical years or from other undesirable features of the wartime medical school program. If the data could be obtained, it would also be important to know whether significant numbers of qualified men have recently been enabled to study premedicine and medicine because of the government subsidization of

past, it would seem to be axiomatic that the ability of a man or woman to pay for a medical education should not be a determining factor in the selection of the student for such study.

An issue of some moment has been raised by the plans of the American Council on Education and other

education in wartime. Several bills now pending in Congress, and the Vannevar Bush report to the President, propose federal scholarships for medical students in the belief that significant numbers of superior men and women are prevented from obtaining a medical education in normal times for financial reasons. Whether or not this has actually been the case in the

organizations, collaborating with the Armed Forces Institute, in which it is proposed to award high school and even college credits to students on the basis of examinations rather than course credits. These plans appear to be well conceived and fully recognize that written examinations cannot measure laboratory performance. It is planned to award credits through

examinations for nonlaboratory courses and for the didactic material in science courses.

Such a program is sound at any time, given adequate comprehensive examinations. It is particularly desirable now, when many veterans should commence academic work at a level commensurate with knowledge and ability rather than at the point dictated by formal course credit.

The awarding of high school credits on the basis of these examinations is entirely in accordance with principles, policies and regulations of the Council. Furthermore, this procedure should not lead to future licensure difficulties, since those states whose laws or practices include high school requirements provide for an alternative "equivalent" of high school work in each instance. Presumably the examinations sponsored by the American Council on Education would constitute such equivalents.

But there is some doubt about the applicability of these examinations as a substitute for premedical nonlaboratory college work under existing regulations. The Council on Medical Education and Hospitals has this problem now under consideration. There should result a common agreement by the Council, the Association of American Medical Colleges and the various state medical licensing boards on this question, so that men and women—particularly veterans—will not be com-

be surveyed for possible inclusion on the Council's list of approved four year schools when senior instruction is under way.

In Washington State, legislation has passed for the establishment of schools of medicine and dentistry under the Board of Regents of the University of Washington, to be located on the university campus in Seattle. There are appropriations of \$450,000 for operation until March 31, 1947 and of \$3,750,000 for construction of the plant, including a hospital. The University of Washington has had several medical basic science departments in its graduate school for some time, which can serve as a nucleus for the new institution. Conferences with the school authorities have been held by the secretaries of the Council on Medical Education and Hospitals of the American Medical Association and of the Association of American Medical Colleges. Definite steps toward consummation of the development are awaiting the appointment of a dean.

Other states now operating schools of basic medical sciences (Mississippi, Missouri, North Carolina, North Dakota, South Dakota and West Virginia) are contemplating expansions to the four year status and have at least authorized surveys of the problem, some of which have been completed. South Carolina, which now has an approved four year school at Charleston, appropriated \$25,000 to survey medical care in the state and prepare plans for an enlargement of the existing four year medical school and construction of a hospital. Florida, with no medical school at present, has provided \$25,000 to conduct a survey into the costs of operating a medical school.

Puerto Rico is projecting a medical school to be operated under the direction of the University of Puerto Rico. Until this institution can be built and put into operation, Puerto Rico has provided funds for scholarships for each of 50 students in each of the next four years, to be awarded to successful applicants to medical schools in this country. Almost all medical schools have indicated a willingness to consider Puerto Rican applicants, with the clear understanding that there is no advance commitment to admit such applicants.

CONSIDERATIONS IN ESTABLISHING A MEDICAL SCHOOL

Unfortunately, some of the current proposals for establishing new medical schools are ill conceived and rest on a failure to understand certain well recognized principles which must guide the thinking about such projects. Some of these considerations, which would seem to be axiomatic, but too often disregarded, are as follows:

1. There is no justification for the establishment of a medical school to meet such an acute temporary emergency as the absence of physicians on military duty.

2. Any overall increased present or postwar need for additional physicians occasioned by the war can be provided by existing approved schools. There is no justification for establishing new medical schools for this purpose. Furthermore, the normal annual number of graduates from existing schools is adequate for the peacetime needs of the country, granted distribution is equitable.

3. The maldistribution of physicians as between the states or between urban centers and rural areas is a problem to be attacked primarily by other means than the production of more doctors in a given state; the rate of production and the distribution of doctors in this country are independent.

TABLE 7.—*Military Status of Medical Students in the United States by Classes, 1944-1945*

	Army	Navy	IV-F	Occup. Defer.	Veter- ans	Un- der 18	Other Men	Women	Total

pelled to study formally what they already have mastered. At the same time there must be a full recognition of the fact that an unwarranted leniency in evaluating the qualifications of an applicant for medical school would do no service to the applicant, the medical school or the public.

NEW MEDICAL SCHOOLS

The Medical College of Alabama is not listed among the complete medical schools, because this Educational Number presents data for the period prior to the commencement of junior work in Birmingham. Therefore the school is still listed with the basic science institutions (table 9, page 48) as the University of Alabama School of Medicine under the deanship of Dr. Stuart Graves. The expansion plans of this school appear to be well conceived and sound. Outstanding leadership has been secured for the Birmingham project in the person of Dr. Roy Kracke, formerly of Emory University. Ample clinical facilities under complete control of the school have been secured: the college holds the deeds to the Hillman Hospital and the Jefferson Hospital with about 1,000 beds, almost all of which are for service cases. Funds and land adjacent to the hospital have been secured for the construction of a basic science building, and the budgetary provisions seem to be adequate at least to commence operations. On recommendation of the Council and of the Association of American Medical Colleges, the school has been awarded contracts by the Army and the Navy for third year instruction, which will have begun by the time this issue of THE JOURNAL is published. The school will

TABLE 8.—Approved Medical Schools in the United States and Canada

These premedical requirements apply to civilian applicants in most instances. All schools will consider completion of the military premedical program, by male applicants on active duty, as fulfilling academic admission requirements.

- * One year (intern) enrollment not included in total column.
- † Sixth year enrollment; Queen's 4; Toronto 10.
- xx One R.M.C. class; figures of other schools are for two graduating classes.
- xx Includes 3.0 in the 5th and 6th years, Canadian schools.

4. Medical education is by far the most expensive form of professional training, requiring an initial outlay and subsequent annual budgets in the early years totaling millions of dollars and not tens or hundreds of thousands. A school whose resources include annual budgets of less than \$350,000, independent of the cost of maintenance of the hospital and outpatient departments, is unlikely to conduct a satisfactory program.

5. The operation of an acceptable four year medical school is far more expensive than the conduct of a basic science medical program.

6. The trend toward more full time clinical instructors is so general that any new school commencing with all or nearly all of its staff on a part time basis is already obsolete.

7. The possession of the M.D. degree and the successful practice of medicine do not, in themselves, indicate that a physician is qualified to teach medical students satisfactorily, even in clinical subjects. Volun-

able to capture a few spare student hours that others had somehow overlooked.

Drastic revisions along the following lines should be made in many institutions:

1. Reduction in scheduled hours in the basic sciences, especially lectures.

2. Provision for free time of students for reading, investigation or the pursuit of special interests. Stimulation of superior students to participate in research.

3. Reduction in the great mass of detail required of students by instructors, possessing no scientific, intellectual or utilitarian value.

4. A closer integration of the basic sciences with one another, in which department autonomy is relegated to its proper position of administrative convenience, and instruction is interdepartmental, emphasizing the human body in health and disease, avoiding the division of the body into its anatomy, its physiology, its pathology, and so on.

* On probation.

† Class will be enrolled in September 1945 under the deceleration program.

‡ Now operating clinical program at Birmingham; see page 45.

§ These premedical requirements apply to civilian applicants in most instances. All schools in the United States will consider completion of the military premedical program, by male applicants on active duty, as fulfilling academic admission requirements.

teer and part time teachers require special training and experience.

8. A hospital well equipped to provide medical care to the people or even satisfactory for internship or residency training is not thereby necessarily satisfactory as a medical school hospital.

9. Medical schools must be so located that there is an ample supply of patients of all kinds, on the one hand, and competent instructors, including specialists, on the other hand.

10. No medical school is worthy of the name which does not carry out some significant research, even though the primary aim of the school is the training of general practitioners.

A failure to observe these generalizations might lead to costly ventures without prospects of accomplishing the ends sought, however desirable those ends may be.

THE MEDICAL CURRICULUM

The present is an ideal time for a reconstruction of the curriculum, since medical education is now in a state of flux. Curricular changes in recent years have been negligible in many if not most medical schools, except for miscellaneous accretions from time to time, sometimes justifiable educationally but too often the consequence of aggressiveness by an instructor who was

5. Closer correlation of basic sciences with the clinical work, so that clinical material is used as a vitalizing aid in the teaching of the sciences, and these in turn are made more significant and useful in clinical medicine.

6. Reduction of didactic and classroom work in the clinical years to the one or two hours a day it warrants.

7. More complete dependence on the case method of clinical instruction, in which the student is an important member of a team solving the problems of diagnosis and therapy in patients studied individually but under adequate supervision by juniors in the wards and seniors in the outpatient departments.

8. A change in faculty attitude toward the clinical student, placing him and his work in a position of greater dignity, so that he does not consider a clinic as a class from 1 to 3 and the writing of his history as a homework assignment. He should be made to feel that he is a physician under supervision and not a schoolboy with classes from 9 to 5.

9. An emphasis on the unknown, and the challenge it presents, equal in importance to the memorizing of textbooks and lectures.

10. The development of research, seminars, discussions and courses in the social and economic aspects of medicine and the distribution of medical care.

Changes of this kind have been made in some areas by some schools. They should be incorporated, along with other reforms, into every curriculum.

APPROVED MEDICAL SCHOOLS

Medical and basic medical science schools in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association are listed in tables 8 and 9 (pages 46, 47 and 48). These tables indicate the quantitative premedical requirements for civilians. The enrolment by classes, including students in a required fifth year of interning or research, and the total attendance, which does not include such fifth year students, apply to the academic session 1944-1945. For most schools this session commenced in September or October 1944 and terminated in June 1945. In other schools this class is still in session. The number of graduates in the past year to June 30, 1945 is also given. For all but ten schools in the United States and four in Canada (see pages 40 and 41 for names of schools) the figures are for two graduating classes, usually in the fall of 1944 and June of 1945. Figures for the sixth year enrolment in two Canadian schools are given in a footnote.

For each school the name of the dean or acting dean is given. In this column there have been fourteen changes in the past year, with new administrative officers at Colorado, Emory, Louisiana State, Wayne, Mississippi, Dartmouth, Western Reserve, Ohio, Vanderbilt, Utah, Vermont, Western Ontario, McGill and Montreal.

Two basic science schools, North and South Dakota, remain on probation for their two year program. Each of these schools is contemplating expansion to a four year status.

Each year the Council conducts as many surveys of already approved schools as it can. During the past year the findings at one of these, the Hahnemann Medical College in Philadelphia, were such as to place the school on probation. Similar action was taken by the Executive Council of the Association of American Medical Colleges.

A medical school is placed on probation when significant but correctable deficiencies are judged to exist in the educational program. Such an institution remains on the list of approved schools maintained by the Council, with its probationary status indicated by a footnote. Hospitals approved by the Council may appoint graduates of such a school as interns, residents or fellows, and all otherwise qualified students entering or attending a school on probation are considered acceptable to the Council, including for licensure purposes.

The Council will give every assistance to this school in its efforts to improve the educational program sufficiently to warrant a termination of the probation.

ENROLMENTS

Enrolment figures for the 1944-1945 session are given in tables 8 and 9 (pages 46, 47 and 48) and recapitulated in table 10. In the seventy-seven medical and basic science schools in the United States there were 24,028 students studying medicine (excluding students in a required fifth or intern year), which is a insignificant decrease of 638, or 2.6 per cent from the enrolment in the preceding session. The 1944-1945 total is slightly larger (about 2 per cent) than the enrolment (23,529) of the class reported in the 1944 Educational Number.

Enrolment totals for the Canadian schools are likely to be misleading, especially if attempts are made to com-

pare the enrolment figures of successive sessions. The low totals in the "preceding session" (table 10) are due to the deceleration process, which is well under way in Canadian schools. As a result, there have not been two full sessions in Canada during the time when there were two full sessions in the United States. The effects of deceleration in Canada are also indicated in the data on juniors in table 8.

There were 390 students in the fifth and sixth years in Canadian schools, which number is included in the "totals" column of table 8 but not in the "total" column of table 10. Intern students in a required fifth year during the 1944-1945 session numbered 606, in the schools of the United States (452) and Canada (154).

In schools offering the complete four years of work, the five schools in the United States with the highest enrolments were Illinois 665, Jefferson 607, Michigan 589, Northwestern 584 and Hahnemann 577. An additional five schools (Tulane, Harvard, St. Louis, New York University and Pennsylvania) had enrolments over 500. The three schools with the lowest enrolments were Woman's Medical College 162, Utah 158 and Vermont 149. Five other schools in the United States

TABLE 10.—Total Enrolments by Classes in Medical Schools of the United States and Canada for the 1944-1945 Session. Students in the intern year are not included

	Fresh- men	Sopho- mores	Juniors	Seniors	Total	Total Preceding Session
69 Medical Schools (U. S.)	6,239	5,716	5,700	5,826	23,481	24,011
8 Basic Science Schools (U. S.)	284	263	547	655
Total (U. S.)	6,523	5,979	5,700	5,826	24,028	24,666
9 Medical Schools (Canada)	759	658	174	547	2,138*	947†
1 Basic Science School (Canada)	25	25	24
Total (Canada)	784	658	174	547	2,163*	971†
Total U. S. and Canada	7,307	6,637	5,874	6,373	26,191	25,637

* Does not include 390 in the 5th and 6th years; these are included in the "totals" column of table 8.

† Does not include 598 in the 5th and 6th years.

(Albany, Syracuse, Bowman Gray, South Carolina and Vanderbilt) had enrolments of less than 200. In Canada the highest enrolment occurred at Toronto with 657 students in its six year program, and the lowest at Alberta with 109 students in its five year course.

During the 1944-1945 session there were two basic science schools with more than 75 students enrolled; these were Alabama (114) and North Carolina (99). The lowest enrolment (in the United States) occurred at Dartmouth, with 24 freshmen and 23 sophomores.

Table 11 gives the number of students enrolled in the United States in the four classes and in internships when required for graduation during the past fifteen years.

During the two sessions conducted since that reported in the 1944 Educational Number there were 25,113 students (1944 second session) and 24,480 students (1944-1945) enrolled. Each of these figures is larger than the total for any preceding year since 1931 despite the fact that students in a required fifth internship year have decreased in numbers in recent years. Also in the past fifteen years the largest enrolment in any one class (freshman to senior) occurred in one or another of the last two sessions shown in table 11. There is no doubt that certain schools have enrolled numbers beyond those justified by their resources and facilities. The number of students in a required fifth internship year has remained practically unchanged during the past three academic sessions.

It should be noted that prior to 1942-1943 the totals shown in table 11 are somewhat higher than the sum of the figures in the various classes. This resulted from certain schools being unable to classify their students strictly into the conventional graded classes, freshman to senior.

TABLE 11.—Students in the United States by Years, Including the Intern Year When Required for Graduation, 1931-1945

	Preclinical		Clinical		Intern Year	Total
1930-1931.....	6,456	5,538	5,080	4,908	1,025	23,007

GRADUATES

The last column of table 8 (pages 46 and 47) gives the 1944 graduates not included in the 1944 Educational Number plus those in 1945 to June 30. These figures are for two graduating classes, usually about September 1944 and June 1945, in all schools except ten in the United States (Arkansas, Howard, Illinois, Tulane, Michigan, Woman's Medical College, Meharry, Southwestern, Baylor and Marquette) and four in Canada (Manitoba, McGill, Montreal and Laval). Therefore, the total of 11,074 graduates in both countries is about double the number graduating in any previous year, because of the accelerated program. The 10,305 gradu-

* Includes figures for schools of the basic medical sciences.

ates from schools in the United States are four times as many as those graduated in 1922. In that year the consequences of reduced wartime freshman enrolments became apparent, as will again be the case three years hence.

The total students and graduates per academic year in this country since 1905 are indicated in table 12. In this table the 10,305 graduates reported here are separated

into the two graduating classes since the Council's last report. For the "1944 second session" classes there were 5,169 graduates and for the "1945 to June 30" classes there were 5,136. Neither of these figures is significantly different from the number of graduates per academic session in the last decade. However, had all four year schools graduated two classes in the past year instead of only 59 out of 69, there would be a considerable increase in the final figure for graduates in table 12. The ten schools having only one graduating class ordinarily graduate about 736 students per session. This number represents approximately the number of additional graduates which will have been produced as a result of increased enrolments in the medical schools of this country, independently of acceleration. For further discussion of the effects of acceleration on the number of graduates see "The Accelerated Program," page 41.

Totals.....	77	24,025	10,305

The University of Illinois continues to graduate the largest number of students, with 167 reported for its one class. The three following schools are next, in order of numbers, each graduating two classes: Northwestern 296 (average 148 per class), Jefferson 289 (average 145) and Harvard 279 (average 140). The smallest numbers were graduated from Baylor 15, Woman's Medical College 29, Albany with 79 in two classes averaging 40, and Bowman Gray 81 in two classes averaging 41.

In the nine Canadian medical schools there were 769 graduates, with five of these schools graduating two classes. The greatest number of graduates was from Toronto, with 245 in two classes. The smallest number, 65 in two classes, received degrees from Western Ontario.

STUDENTS AND GRADUATES BY STATES

The seventy-seven medical and basic science schools in this country are located in thirty-six states and the District of Columbia. The numbers of schools, students and graduates in these states are shown in table 13.

Each of five states enrolled more than a thousand students in their schools and graduated (mainly in two classes) more than 500. In order, these states are New York, nine schools, 3,124 students, 1,465 graduates; Pennsylvania, six schools, 2,692 students, 1,208 graduates; Illinois, four schools, 1,814 students, 741 graduates; Massachusetts, three schools, 1,183 students, 593 graduates; California, four schools, 1,161 students, 510 graduates. The twenty-six schools in these five states account for 42 per cent of the entire student enrolment in this country and 44 per cent of the graduates.

Six of the states with basic science schools had no graduates, since there are no four year medical schools in those states. Four states with one school in each had fewer than 100 graduates: Arkansas 63 in one graduating class, Vermont 68 in two classes, Utah 73 in two classes and South Carolina 96 in two classes.

GEOGRAPHIC SOURCES OF FRESHMEN STUDENTS, 1944-1945

In table 14 is indicated the residence of students in the 1944-1945 freshman class of each medical and basic science school in the United States. The actual states in which the out of state students reside are not given, all students residing in states other than that in which their schools are located being grouped together in the column "other states." Included in the table are 6,523 freshmen in the schools of this country and 784 in Canadian institutions, or 7,307 in all. In the United States 46 per cent of all 1944-1945 freshmen came from elsewhere than the state in which they attend school. Almost all, or 2,899 of these 3,037 students, came from other states of the Union. A few (86) came from the territories and possessions of the United States, 13 were from Canada, and from foreign countries there were 39.

A listing of schools admitting more out of state residents than residents of the state in which the school is located would give a false impression of normal policies. Although freshmen are selected by committees of deans, there is little or no selection of specific students by specific schools, or schools by students, especially in the Army Specialized Training Program. As a result, several state schools normally limiting selections almost entirely to residents now find themselves with many out of state residents. No school in this country was without at least one nonresident freshman in this class.

Tulane enrolled the largest number of freshmen (11) from territories and possessions, and the College of Medical Evangelists admitted the most Canadians (8). Freshmen from foreign countries numbered 6 at Tulane and 6 at Michigan.

In the Canadian school freshmen classes there were 784 students, of whom 730, or about 93 per cent, were residents of Canada. In addition there were 30 freshmen from this country and 24 from foreign countries. McGill enrolled the largest number, 25 from the United States and 12 from foreign countries.

There are twelve states in the Union in which no medical or basic science schools are located. These are listed in table 15, which also gives the number of freshmen from each of these states enrolled in medical schools, as well as the number of schools they attended. There were 611 such freshmen, over 60 per cent of whom came from New Jersey and the state of Washington. From New Jersey there were 252 freshmen in forty-four schools. The greatest number, 31, were

in New York University. From Washington there were 122 in thirty-nine schools, with 23 attending Oregon. There were no freshmen from Nevada in the 1944-1945 class.

It is of interest to compare the number of medical students in 1944-1945 freshmen classes in this country

per hundred thousand of population from the twelve states without medical schools and from the country at large. In the country at large there were just 5.0 freshmen enrolled per hundred thousand inhabitants, employing the 1940 census figures. Exactly the same ratio applies for the total freshman registration from these twelve states as a group and their population. New Jersey, without an approved medical school of its own, sent 6.0 men or women per hundred thousand of its population to approved medical schools elsewhere. Washington had the even higher ratio of 7.0 per hundred thousand. These figures would seem to indicate that there is no justification for the argument frequently advanced in some states that "we need a medical school in our state because our boys and girls cannot gain admission to out of state institutions." These figures suggest that these students have as great a chance for admission as do those students residing in a state which does have a medical school within its borders. Justification for developing a new medical school must rest on other grounds.

INTERNSHIPS REQUIRED BY SCHOOLS AND STATES

The medical schools requiring the internship for the M.D. degree are listed in table 16. Only six schools in the United States and four in Canada include this

requirement. There has been no change in this list in the past two years.

In the year 1944-1945 there were 452 students of schools in the United States and 154 students from Canadian institutions, a total of 606, reported as engaged

in this work in fulfilment of the internship requirement for the M.D. degree.

Although relatively few schools now require the internship for the M.D. degree, this is required for licensure by twenty-three states, the District of Columbia, Alaska, Hawaii and Puerto Rico. Table 17 lists these states and also indicates the relationship of this requirement to the wartime nine month internship. At least for the emergency period, eight states and Alaska will accept the shortened internship. Twelve states, the District of Columbia and Puerto Rico require an additional three months in a civilian hospital or military service and will withhold the license until this is completed. However, they will permit applicants for licensure to write the examination on completion of the nine month internship. In three states it is necessary to complete the full year of internship, three months of which may be in the military service, before becoming eligible for the licensure examination. Officers desiring licensure in these states (Illinois, New Hampshire and New Mexico) must seek furloughs to take the exami-

TABLE 17.—Relationship of the Nine Month Internship to Licensure in All States Requiring an Internship

	Washington ¹	
	Wisconsin	

Hawaii, which requires an internship for licensure, has not reported on the relationship of this requirement to the shortened internship. Some states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants. 1. Will also give examination on completion of the medical course but withhold license until internship is completed. 2. Military medical service must be in a military hospital.

nations or delay the procedure until after discharge. Four states specifically stipulate that the three months of military service must be in a military hospital to be acceptable.

Some states require the internship of graduates from schools abroad and applicants for reciprocity or endorsement. The licensing boards of Illinois, Michigan, North Dakota, Pennsylvania and Washington require the internship to be a rotating service, while New Jersey recommends this type of service.

Some medical schools and licensing boards maintain their own list of hospitals acceptable for intern training, but the list of approved internships compiled by the Council on Medical Education and Hospitals is generally used. The Veterans Administration has indicated that all educational institutions included on the various approved lists of the Council on Medical Education and Hospitals of the American Medical Association, including medical schools and house officer hospitals, will be acceptable as institutions eligible for the training of veterans under the "G. I. Bill of Rights."

DISTRIBUTION BY SEX

Students in the 1944-1945 academic session and graduates during approximately one year, ending June 30, 1945, are classified according to sex in table 18

for all medical and basic science schools in the United States and Canada. The enrolment was 25,001 men and 1,580 women. Graduates totaled 10,513 men and 561 women. All but six of the eighty-seven schools reported

Totals	25,001	1,580	10,513	561

women students. Five of these have not admitted women in recent years: Georgetown, Harvard, St. Louis, Dartmouth and Jefferson. North Dakota, which reported no women in the 1944-1945 classes, has had

women students within the past few years. All Canadian schools had women students enrolled.

Women students in the United States numbered 1,352 as compared with 22,676 men. In Canada there were 228 women and 2,325 men students. In the one medical college for women only there were 162 students and 29 graduates. Nine other schools, including two in Canada (Illinois, Michigan, New York Medical, New York University, Hahnemann, Temple, Wisconsin, Toronto and McGill), had more than 30 women students.

There were 561 women graduates from seventy-two of the seventy-eight four year medical schools. Graduates numbered 514 women and 9,791 men in the United States. In Canada there were 47 women graduates and 722 men.

Table 19 shows the distribution of students and graduates in the United States and Canada classified by sex for a period of ten years—actually, eleven academic sessions, two of these having been completed by most schools in the past year. The current (1944-1945) enrolment of women, 1,580, exceeds that of any class in the last decade, although this increase is not yet apparent in the figures for women graduates, per

TABLE 19.—*Distribution by Sex in the United States and Canada, 1936-1945*

academic session. Women graduates have not changed appreciably in numbers in the past ten years.

Table 20 gives the percentages of women medical students and graduates in the United States since 1905. For the second academic session reported in this issue, since the 1944 Educational Number, the percentage enrolment of women has risen to 5.6. This is a higher proportion of women enrolled in medical schools than at any other time in the last twenty years. The percentage of women graduates in the past year was equalled or exceeded several times in the past decade.

We may expect increases in the enrolment of women in the next entering classes, with the current limitations on the supply of qualified men. However, it is not apparent that there is a large reservoir of qualified women students interested in and prepared to study medicine. The ratio of women applicants to women accepted in medical schools has been about the same as the ratio for men. Should schools determine to admit a considerably larger proportion of women next year, they would probably be unable to do so without accepting students with qualifications inferior to those required in the past from either men or women.

LOAN FUNDS AND SCHOLARSHIPS

Since about 80 per cent of the students in medical schools are now being financed under the Army and Navy programs, the need for student loans and scholarships has been greatly reduced. At the present time needy and deserving civilian students can probably be

adequately provided for locally. In many instances university and college funds for these purposes have accumulated from lack of demand for them. Such funds should be carefully conserved, because of the likelihood that there will soon be a higher percentage of civilians in our medical schools. Since the accelerated program must be continued to fulfil Army and Navy agreements, financial hardships may be encountered by the increasing number of civilians.

Recently there have been several proposals that federal funds be made available for medical student scholarships. It would be preferable to have such aid made available as loans rather than as outright scholarships, since the practice of medicine is reasonably remunerative. Competent medical students should have sufficient confidence in themselves to be willing to borrow money for their education.

PART TIME, SPECIAL AND GRADUATE STUDENTS

Part time, special and graduate students are excluded in all of the foregoing tabulations and statistics. Special students include those carrying work in such fields as public health, physicians reviewing for specialty boards examinations and students preparing to become physical therapy or clinical laboratory technicians. Curriculums in these and other fields may involve medical courses.

During the 1944-1945 session there were 129 part time or special students and 140 graduate students enrolled in some of the medical courses in forty medical and basic science schools in this country and Canada. These numbers represent still further decreases below the figures of a year ago. The decreased enrolment of graduate students is another reflection of our national wartime policy of failing to provide for the training of scientists. In 1940-1941 there were 1,167 graduate students in our medical schools. Last year's 140 is only 12 per cent of this number. The Selective Service System and the Army and Navy have insured a deficiency in medical students, in quantity or quality, in the next few months or years. They have also provided for an even more prolonged deficiency in medical school teachers and investigators in the basic sciences.

GRADUATES WITH BACCALAUREATE DEGREES

At the present time no school in the United States requires a degree for admission, although one school (Tufts) requires four years of premedical work. In

Canada, Montreal and Laval require the degree. Two schools (Louisville and Vanderbilt) require the student to earn a bachelor's degree during the first year in medical school. Yet 79 per cent of the graduates from seventy-eight four year medical schools in

the United States and Canada also held baccalaureate degrees, as shown in table 21. This does not include those earning the B.S. in medicine, who are presented in the next section.

In the United States 8,431 (or 80 per cent) of the 10,305 medical graduates also held bachelor's degrees and in Canada 352 (or 45 per cent) of the 769 medical graduates also held the additional degree. All the graduates of eight schools (Stanford, Minnesota, Cor-

nell, Oregon, Jefferson, Vanderbilt, Vermont and Wisconsin) held both degrees. Likewise, all the graduates of Laval held both degrees.

GRADUATES WITH THE B.S. IN MEDICINE

There were 218 graduates of medical schools in the United States in 1944-1945 who also at some point during their medical course received a bachelor's degree referred to as a B.S. in medicine. Certain of the graduates of eleven medical schools received this degree. The largest single group to receive the degree were 45 graduates of the University of Texas. Northwestern awarded 34 and Western Reserve 33. Other schools granted fewer than 30 and three schools less than 10. None of the graduates of Canadian medical schools in 1944-1945 obtained this degree.

FEES

The eighty-seven medical schools and basic science schools in the United States and Canada have been arranged in five groups in table 22 according to the tuition fees charged resident students for the session 1944-1945. The data are based on the average tuition fee charged for the complete medical course and includes such minor charges as those for matriculation, breakage, diploma and graduation.

There is a continuous upward trend in tuition fees. No school now charges less than \$100 for the year. The average tuition fee charged by medical schools in the past five years has increased from \$378 in 1940 to \$415 in 1945:

Thirty-three schools in the United States and five in Canada make an additional charge for nonresidents. The Army and Navy pay nonresident fees for their

TABLE 22.—Fees, 1944-1945

students. These sums vary considerably in amount. Toronto charges \$5 for the first year students and \$10 for others. Three schools charge \$50 or less annually. Three schools have nonresident tuition fees of \$350 or more: Oklahoma \$350, Louisiana State \$400 and Georgia \$445.

APPROVED INTERNSHIPS AND RESIDENCIES FOR VETERAN AND CIVILIAN PHYSICIANS

As the time approaches when greater numbers of medical officers will be returned to civilian life, it is becoming increasingly important that the medical profession and hospitals continue their efforts to maintain and develop adequate facilities and opportunities for the continued training of veteran and civilian physicians. Much has already been accomplished; studies carried out by the Council on Medical Education and Hospitals in collaboration with the Committee on Postwar Medical Service indicate that the required number of educational programs have now been developed in several fields. Other services, however, will require further expansion to meet the anticipated need of the postwar period.

Under normal peacetime conditions the approved hospitals in the United States provide opportunities for approximately 5,300 residents. After the war emergency this number will be augmented by a large group of medical officers who have recently indicated their desire for further residency training. From the initial report on Results of Pilot Questionnaire to Physicians in Service¹ it was estimated² that 10,260 medical officers would request full time educational assignments of more than six months' duration. This estimate has since been revised in view of the more recent report on Postgraduate Wishes of Medical Officers,³ in which it was indicated that 12,534 desire more than six months' training. Combining this figure with the normal civilian complement of 5,256 residents as reported in 1941, it might appear that hospitals may be called on to furnish a total of 17,790 residencies in the immediate postwar period. Since available services totaled 5,796 in 1943, the number of additional residencies required would be 11,994, assuming that rapid demobilization occurs. If considerable time is required, however, it has been estimated that 5,727 additional places

will be needed to supplement the facilities regularly available. Compared with 1943 the total requirement of 11,523 represents an increase of approximately 100 per cent in the number of residencies necessary for veteran and civilian needs.

The extent to which educational facilities have already been expanded is illustrated in table 23, which represents approved internships and residencies within the continental limits of the United States, not including the training programs of army and naval hospitals. This table, which classifies the educational services by states and specialties, contains also comparative data for 1943 as well as the estimated number of residencies required for postwar training. Here the cooperation of hospitals is readily apparent in the reported increase of approved residencies to 7,625 as compared with 5,796 in 1943. This is an expansion of 32 per cent since 1943, but it also represents an increase in available facilities of 45 per cent if compared with the normal prewar number of residents in approved hospitals. In relation to the total requirement of 11,523, however, the present available facilities constitute 66 per cent, or two thirds of the estimated needs.

The required expansion of residencies in specialties is not uniform in all fields. Comparing the estimated total in table 23 with the available facilities in 1943, it will be found that an increase of 122, 132 and 137 per cent may be required in obstetrics-gynecology, dermatology and surgery respectively, 55 to 84 per cent in anesthesia, radiology, pediatrics, urology, ophthalmology-otolaryngology, orthopedics and internal medicine, and 23, 36 and 41 per cent in neurologic surgery, psychiatry and neurology, and pathology. In the mixed residency or general review group, where the anticipated increase is 458 per cent, it is necessary to take into consideration that a large part of this demand will probably be absorbed by the approved internship hospitals which are likewise accredited for mixed resi-

1. J. A. M. A. 125: 558 (June 24) 1944.

2. J. A. M. A. 126: 254 (Sept. 23) 1944.

3. J. A. M. A. 127: 759 (March 31) 1945.

dencies. Plastic surgery records a required expansion of 650 per cent, but the actual number of services is small and may involve training in some of the related surgical fields.

From the number of available residencies in table 23 it is apparent that the estimated requirements in anesthesiology, neurologic surgery, pathology and psychiatry and neurology can practically be fulfilled by the expansion of residencies already reported in approved hospitals. Obstetrics-gynecology, dermatology and surgery seem to require a further expansion of 74, 55 and 79

expanded in accordance with available clinical and teaching facilities. Approximately 30 per cent have now replied, and their reports on the expansion of approved residencies are included in the present discussion. Counting also the new services under consideration, it is probable that this group may be able to provide altogether a total of 2,382 additional residencies.

A new list of Approved Residencies and Fellowships for Veteran and Civilian Physicians has recently been prepared. These services, investigated and approved by the Council, are considered in position to furnish

x. Includes 91 residencies in other fields. * Includes fellowships. † Includes cardiology, communicable diseases and tuberculosis.
‡ Includes fractures. § Includes malignant diseases, thoracic surgery and traumatic surgery.

per cent in comparison with present facilities. In medicine the needed expansion is now 46 per cent, ophthalmology-otolaryngology 43, orthopedics 34, pediatrics 30, radiology 20 and urology 26 per cent. It should be noted that many of the hospitals approved for residency training have not yet developed their educational service to full capacity and are therefore in position to organize new training programs or effect further expansion of residencies already approved. Internship hospitals which have not previously engaged in residency training are also in many instances developing satisfactory educational programs in response to the increased need of the postwar period. All approved intern and residency hospitals have been asked to indicate the extent to which educational services can be

acceptable residency training in accordance with standards adopted by the American Medical Association. In practically all fields these training programs have been reviewed in collaboration with the respective specialty boards. The list includes also the expanded number of residencies now available in those approved hospitals which have completed their plans to provide further opportunities for returning medical officers. Many additional residencies recently organized or in process of development may soon be added to the approved list. Thus there is every indication that, with the continued cooperation of hospitals and medical staffs, adequate graduate educational facilities will be available to all medical officers who desire further training after discharge.

The residency list as well as the newly prepared list of Approved Internships will be included in the reprint edition of the Educational Number and will be given wide distribution to medical schools, state boards of medical examiners, specialty boards and other agencies. Lists will also be available to medical officers and other physicians on request.

The intern list contains the names of 734 institutions exclusive of army and naval hospitals. Under normal peacetime conditions these institutions would be able to accommodate 8,360 interns. Prior to the war most of these positions would have been filled even though the annual graduating class of medical students did not exceed 5,500. Nearly 2,300 places, it should be noted,

were occupied by interns who remained for a second year of service or held an original internship appointment of more than twelve months. In the postwar period it is anticipated that most of the internships will continue as one year assignments followed by assistant residencies and residencies for those who desire further hospital training. Thus there is ample assurance that sufficient facilities will be available to returning medical officers who may wish to obtain an internship, supplement their previous nine months training or secure advanced assignments as second year interns or general resident physicians. All internship hospitals approved by the Council are likewise accredited for general or mixed residencies.

POSTGRADUATE CONTINUATION COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

While many scientific meetings and other programs of graduate medical education were canceled at the request of the Office of War Mobilization, nevertheless the Council on Medical Education and Hospitals has been able to provide a great deal of information regarding opportunities available for postgraduate study. An analysis of questionnaires returned by 21,029 medical officers concerning their postgraduate¹ wishes indicates that approximately 20 per cent of the group will desire short term refresher and review courses of less than six months' duration. The studies of the Council on Medical Education and Hospitals indicate that greatly expanded facilities will be available for this type of training for both veteran and civilian physicians but that there is an acute need to provide full time courses of about three months' duration. Reports from medical schools, hospitals, medical societies and other agencies give assurance of continued expansion of educational programs in anticipation of postwar needs. The demand for all facilities for instruction is greater than it has ever been. The individuals who will give or have given so generously of their time to participate in the instructional programs constitute a large and distinguished faculty of medicine. The efforts of individual physicians with their increasing personal responsibilities and institutions and other agencies with greatly depleted staffs to assist in the presentation of these opportunities is noteworthy.

The Council on Medical Education and Hospitals publishes semiannually advance information concerning postgraduate continuation courses. These include courses in a wide variety of fields in clinical medicine and the basic sciences. The courses are for variable periods from a few days to several months. Some are concentrated full time courses and others are part time. In THE JOURNAL for July 7, 1945 there were listed 493 courses which will be offered during the period July 1, 1945 to Jan. 16, 1946. Many of these courses are not scheduled for any definite date, are arranged to suit the convenience of the physician student and may be repeated throughout the year. Therefore the 493 opportunities listed represent many course sessions beyond this number. The analysis by Colonel Lueth² indicated that one of the most acute needs for expansion of postwar educational opportunities pertained to full time review and refresher courses of about three months' duration.

During the current six months 162 additional courses have been arranged as compared with the compilation

of such opportunities for the first half of the current year. The courses listed in the July 7 issue of THE JOURNAL² are offered by hospitals, medical schools, graduate medical schools or other agencies in twenty-six states and include forty-two specialty or subspecialty subjects. There appears to be adequate geographic distribution. Institutions offering continuation courses for veteran and civilian physicians are invited to announce such courses in these semiannual lists compiled by the Council.

It should be noted that these opportunities are offered in addition to the noteworthy in-service plans being formulated by the Army and the Navy.

In the following paragraphs mention is made of some of the recent and noteworthy developments in postgraduate education. An analysis of the courses offered during the period July 1, 1944 to June 30, 1945 is also presented.

RECENT DEVELOPMENTS

The three month full time courses being developed in a number of medical schools will fulfil a great demand from physician veterans who will wish an intensive review. Especially appropriate courses of this kind have recently been organized by the medical schools of the universities of Wisconsin, Illinois and Iowa.

Courses varying from three days to three weeks conducted wholly or on an individual basis are offered by the California Tuberculosis and Health Association. The instruction covers clinical diagnosis and treatment of tuberculosis. Two institutes are being planned for the fall of 1945 for physicians on the reading of miniature films. The course as planned will run five days in Los Angeles and five days in San Francisco.

The Department of Medicine of the Graduate School of the University of Florida, in conjunction with the Florida Medical Association and the State Board of Health, presented its Thirteenth Graduate Short Course for doctors of medicine June 25-30 with a total attendance of 202, consisting of both civilian physicians and physicians in the armed forces.

The Cook County Graduate School of Medicine has plans to accommodate returning medical officers by offering its large variety of courses at more frequent intervals. The length of the courses varies from two weeks to six months. A total of 1,114 physicians were in attendance at this institution during the last year.

1. J. A. M. A. 127:759 (March 31) 1945.

2. J. A. M. A. 128:751 (July 7) 1945.

The extension courses of the Kentucky State Medical Association provide for lectures to physicians at various places in the state.

The University of Michigan Department of Postgraduate Medicine is completing plans for three courses of two months each, probably continuing throughout the year, for returning medical officers especially.

The training program conducted since January 1942 in the Mayo Clinic under the auspices of the Mayo Foundation for Medical Education and Research has been temporarily discontinued. During the time these three months' courses have been in effect in the various fields over 1,200 officers have been assigned to them by the Army, Navy and Public Health Service. Pending the reestablishment of a postgraduate program at the Mayo Clinic, physicians are welcome to attend clinics, lectures and seminars any time for as long as they wish to remain.

At the Center for Continuation Study at the University of Minnesota a number of refresher courses have been given. The state department of health participated in many of these courses.

A total of 872 physicians enrolled in the New York Post-Graduate Medical School from July 1, 1944 to June 30, 1945. A considerable number of them enrolled for more than one course, as is shown by the fact that the number of registrations totaled 1,130. A number of new courses have been organized for the coming year which will be of particular interest and value to returning medical officers. Preparations are being made to accommodate as many as the physical facilities of the school will permit.

The annual summer graduate course in ophthalmology under the auspices of the University of Rochester School of Medicine and Dentistry, which was discontinued several years ago, was resumed this year.

The North Carolina State Board of Health sent 25 practicing physicians for two weeks' stay at the Southern Pediatric Seminar at Saluda, N. C. in July of this year. Funds for these scholarships were provided by the United States Children's Bureau. This group conducted its twenty-fifth annual seminar this year.

The Pennsylvania Tuberculosis Society offers three scholarships to practicing physicians in the state for the course at the Trudeau School of Tuberculosis. This consists of a six weeks postgraduate course at the Trudeau School at Saranac Lake, N. Y. It is the purpose of the Pennsylvania Tuberculosis Society in offering these scholarships to afford physicians in general practice in communities more or less distant from the metropolitan centers and who have not had special training or experience in tuberculosis opportunity to obtain training.

The Graduate Medical Course in caudal analgesia offered at the Philadelphia Lying-In Hospital is to be transferred to the University of Tennessee College of Medicine at Memphis in October 1945. The reason for this transfer is to provide more clinical material for increasing enrolments. The course will cover a period of two weeks and will be given continuously. In the past two and one-half years during which this course has been in operation in Philadelphia, 550 physicians from forty-four states and twenty-nine foreign countries have been trained.

Five courses have been arranged for periods of ten days to six months at the Institute for the Control of Syphilis of the University of Pennsylvania.

The Southwestern Medical College at Dallas, Texas, is prepared to offer two postgraduate courses, each of two months' duration. In addition, the Dallas Southern Clinical Society plans to conduct brief courses of one to two weeks' duration.

The Virginia Society of Ophthalmology and Otolaryngology sponsors a short postgraduate course each December, given in the even years at the University of Virginia School of Medicine at Charlottesville and in the odd years at the Medical College of Virginia in Richmond.

Courses of twelve weeks designed especially for the men who are returning from service who are not interested in the specialties are offered by the University of Wisconsin Medical School. Clinics in four cities were offered in the spring of 1945 by the State Medical Society of Wisconsin. More than 200 physicians attended these clinics.

A survey is being conducted by the American Gastroenterological Association with a view to sponsoring postgraduate work for the returning medical officers.

It was necessary to cancel the annual postgraduate medical teaching venture sponsored by the Inter-State Post-Graduate Medical Association, which draws an attendance of several thousand. Likewise the 1945 Clinical Congress of the American College of Surgeons, as well as its War Sessions, which last year attracted 17,000 physicians, were canceled.

The American Academy of Ophthalmology and Otolaryngology is again offering a home study course in ophthalmology or otolaryngology. The value of these home study courses is recognized by the specialty boards, and registrants are recommended for residencies and candidates for board certification, although it is specifically understood that completion of the academy courses does not necessarily fulfil the requirements of the boards for fundamental training.

The excellent opportunities outlined are mentioned to present the variability of the courses being offered throughout the country. *THE JOURNAL* for July 7, 1945 presents these and many others in detail. Such institutions as Tulane, Hopkins, Harvard, Tufts, New York Eye and Ear Infirmary, the New York Medical College, the New York Polyclinic and the University of Pennsylvania are continuing to offer organized courses. These examples emphasize the fact that, even though the staff physicians of all institutions are sorely taxed, they have been able to develop or continue opportunities for graduate education.

ANALYSIS OF COURSES OFFERED, 1944-1945

In presenting this analysis of postgraduate courses which have been offered during the annual period July 1, 1944 to June 30, 1945 the statistical summaries are divided into three groups: courses in which instruction was offered to physicians in or near their home communities, courses providing ample facilities for clinical instruction and, lastly, a group including clinical conferences, graduate assemblies, study courses and so forth.

Five states (Kentucky, Michigan, Minnesota, Oklahoma and Wisconsin) provided opportunities for physicians to continue professional study in or near their home communities. Subjects of these courses included general medicine, industrial health, neurology and psychiatry, ophthalmology, otolaryngology, pediatrics, poliomyelitis and surgery.

Agencies which were active participants in providing these opportunities, either independently or jointly,

included state and county medical societies in Kentucky, Michigan, Oklahoma and Wisconsin, the two medical schools in Michigan and the American Academy of Ophthalmology and Otolaryngology. Other agencies included the state departments of health in Michigan and Oklahoma, the Commonwealth Fund and the Horace H. and Mary A. Rackham Fund.

The courses varied in length from one day sessions to courses extending over nine months. There was a total of eight courses given. The type of instruction given was both didactic and clinical. Two courses were home study in nature. The instructors were chosen from physicians practicing in the state in which the courses were offered as well as from out of state men. Fees ranged from \$1 to \$9, while for two courses no fee was charged.

The attendance reported for these eight courses was 2,365. The attendance for such opportunities in 1944 was 3,955 for courses in eight states. Transportation and other difficulties greatly curtailed the sponsoring of these courses itinerant in nature, but nevertheless the value of this type of instruction should not be underestimated.

In centers where ample clinical facilities are available, 618 graduate courses of less than one year's duration were offered in twenty-three states and the District of Columbia. These states and the number of courses which were given in each during 1944-1945 are as follows:

Alabama.....	1	Iowa.....	1	North Carolina....	1
Arkansas.....	4	Kansas.....	2	Oregon.....	1
Colorado.....	1	Louisiana.....	9	Ohio.....	1
Dist. of Columbia..	13	Massachusetts.....	34	Pennsylvania.....	14
Florida.....	1	Michigan.....	15	South Carolina.....	2
Georgia.....	1	Minnesota.....	9	Texas.....	4
Illinois.....	165	Mississippi.....	1	Virginia.....	2
Indiana.....	1	New York.....	302	Wisconsin.....	13

While the majority of the courses were in various subjects as the demand seemed apparent, specific courses in general medicine were offered in forty-eight instances, neurology and psychiatry in forty-five, ophthalmology in thirty-nine, general surgery in thirty, obstetrics and gynecology in twenty-six, cardiology in seventeen, dermatology and syphilology, gastroenterology and otolaryngology in fifteen, electrocardiography in twelve and allergy in eleven. Ten courses or fewer were offered in anatomy, anesthesia, arthritis, bronchoscopy, cystoscopy and endoscopy, diabetes, diseases of the chest, electroencephalography, endocrinology, fractures, gastroscopy, gonioscopy, hematology, industrial medicine, legal medicine, neurosurgery, orthopedics, otology, pathology, pediatrics, physical medicine, poliomyelitis, proctology, public health, radiology, therapy, tropical medicine and urology.

Sixty-six agencies or combinations of agencies participated in the planning of the program. Three graduate schools of medicine played the most prominent part in offering courses of this nature. Of the medical schools of the country, seventeen have given courses for practicing physicians during the year. Two state medical associations, five state boards of health and three city or county medical societies made contributions. In nine instances hospitals were the agencies offering short periods of study. Other agencies included three special societies, the American College of Physicians, the United States Public Health Service, Research and Study Club of Los Angeles, Catholic University of America, Institute for Psychoanalysis, Chicago, Boston Psychoanalytic Institute, New York Academy of Medicine, Edward L.

Trudeau Foundation, University of North Carolina School of Public Health, Philadelphia Psychoanalytic Institute, Texas Academy of Science, Department of Medicine of the Graduate School of the University of Florida, Southern California Medical, Dental and Pharmaceutical Association, Rockefeller Foundation, Topeka Institute for Psychoanalysis, Commonwealth Fund, Harrington Fund, Lillia Babbit Hyde Foundation, Lasker Foundation, William Buchanan Foundation and Horace H. and Mary A. Rackham Fund. Columbia University, through the New York Post-Graduate Medical School and affiliated hospitals, offered the greatest number of courses.

The length of these courses varied from seven and one-half hours to twenty-four weeks for 323 courses. Ninety-five courses were full time opportunities ranging from one month to six months. Of the remaining 200 courses, 156 did not specify the length of the course, 20 were arranged courses, length not specified. There was a three year course and two courses of a year in length. The remainder specified the length of the course in semesters or quarters.

The description of these intensive courses gave evidence that the type of instruction was both clinical and didactic. In presenting postgraduate courses, medical school facilities were used for 405 courses, hospitals for 264 and clinics for 198. In many instances two or all three of these sources were used in presenting an individual course. Hotels and other facilities were used for 35 courses. The faculties of the medical schools served as instructors in 462 courses. Additional instructors were specialists in their fields chosen mainly from physicians residing within the state in which the course was given but including as well physicians from outside the state.

Courses were offered during every month last year, and in 69 instances they were arranged to suit the convenience of physician-students. There were 115 courses available for specialists only. Fees varied considerably, ranging from \$1 to \$800. For 14 courses no fee was charged. No fee was charged medical officers in 12 other courses.

The attendance reported for 611 of the 618 courses given last year was 9,833. In 1944 the attendance for 364 such courses was 8,888. As has previously been stated, 493 opportunities are being offered for the period July 1, 1945 to Jan. 16, 1946. Many of these have but recently been organized for the benefit of returning medical officers. If all physicians desiring further training are able to take advantage of the opportunities being offered, it can be estimated that the attendance for 1945-1946 will double that reported this year.

Clinical conferences and graduate assemblies of less than five days were held in twelve states. Many of these opportunities scheduled for the first six months of 1945 were canceled at the request of the Office of War Mobilization. The twelve states in which such studies were presented were Connecticut, Illinois (4), Michigan, Missouri (3), Nebraska, New York, North Carolina, Ohio, Pennsylvania, Texas (2), Virginia and West Virginia. The specialties covered were allergy, anesthesiology, dermatology and syphilology, industrial medicine, general medicine, neurology and psychiatry, neurosurgery, obstetrics and gynecology, ophthalmology and otolaryngology, pediatrics, physical therapy, radiology and tuberculosis. Twenty agencies participated in the instruction. The assemblies were held in centers with facilities for clinical and practical work and for

scientific exhibits. Instruction was both didactic and clinical. The facilities of hospitals, clinics and medical schools were used. The instructors included physicians residing in the state where the assembly was held, physicians from other states and members of the professorial faculties of medical schools. One or more assemblies were held in each month from September to April inclusive. Registration fees ranged from \$2 to \$15, while no fee was charged in two instances and four were free to medical officers. The total recorded attendance was 6,847. The total recorded attendance for all courses in 1944 was 19,045.

The travel restrictions have affected considerably the latter group as well as opportunities of an itinerant nature. The organized courses have been affected to a lesser extent. It is to be hoped that physicians may be able to avail themselves of a variety of courses scheduled for the future. The attendance for most of these courses is limited in number and is not affected by the edict of the transportation authorities.

For all three types of training offered during 1944-1945 the attendance was 18,206. This figure excludes physicians who were enrolled for courses of longer than a year's duration as well as those serving internships and residencies and physicians who attended the Wartime Graduate Medical Meetings, and courses arranged by the military authorities for medical officers.

WARTIME GRADUATE MEDICAL MEETINGS

Under the auspices of a committee representing the American Medical Association, the American College of Physicians and the American College of Surgeons a series of wartime graduate medical meetings have been held for the past several years. The administrative work is done entirely by a central committee with headquarters at the office of the American College of Physicians. Locally the programs have been arranged for and conducted under the supervision of regional chairmen and local committees. The central committee and regional chairmen have been emphasizing programs available to the men in military service rather than programs for the civilian physician. The major purpose of these activities is to maintain contact with civilian medicine. The central committee has initiated a program whereby a team of physicians covers a circuit of more or less isolated military installations in order to meet the needs that could not be met otherwise. The activities of these Wartime Graduate Medical Meetings continue, although it is probable that they will terminate at the conclusion of hostilities or as soon thereafter as demobilization takes place.

Programs, often more than one, were arranged in every state during the past year. These programs were arranged in one or more Army or Navy installations within a state and varied from a single lecture to a series of talks in a given center. The attendance at these sessions has not been reported routinely, but reports made by the Central Committee to the Committee on Postwar Medical Service gives evidence of the continued usefulness of these meetings.

POSTWAR EDUCATIONAL PLANS OF STATE MEDICAL SOCIETIES

Fourteen state medical societies have initiated or are planning programs of continuation education for physicians returning from military service. Some of these plans are in the formative stage, while a few states

have developed extensive programs. Other states have reported that they are not planning statewide programs of graduate education but have the assurance of the medical schools of the state that veteran physicians will be provided the type of graduate training they may desire. In some of the smaller states the personnel is not available to develop such opportunities.

The progress to date in the fourteen states referred to briefly is as follows:

The California Medical Association has appointed a Committee on Postwar Plans and has inaugurated studies of hospital internships and residencies as an initial stage of their responsibility and the foundation for the development of educational programs for returning physicians.

In Connecticut the Committee on Medical Care and Health of the State Postwar Planning Board designated a Subcommittee on Intern Curriculum to study intern service and intern training in Connecticut hospitals. This subcommittee brought out a report in November 1944 and included recommendations intended to serve as a guide to hospitals in improving the quality of internships available.

In Indiana postwar educational work is being done through the Indiana University School of Medicine. At the request of the Tippecanoe County Medical Society the university is conducting an extension course in postgraduate medical instruction at St. Elizabeth's Hospital, Lafayette, referred to as the "Lafayette Experiment." In this venture the physicians of Tippecanoe County are cooperating.

The Kansas Medical Society is attempting to raise through voluntary contributions a fund of \$100,000 to be used at the direction of its Committee on Graduate Education for the postwar training of Kansas doctors who are returning from the armed forces and for the establishment of programs of postgraduate instruction for the use of all members of the society. Various types of courses will be offered by the University of Kansas School of Medicine. The society in cooperation with the State Board of Health and the Kansas Hospital Association plan a comprehensive statewide study of hospitals. Plans are also under way to subsidize a program of postgraduate courses to be offered on the circuit plan in forty-five to fifty different centers in the state.

Extension courses are under way by the Kentucky State Medical Association which provide for lectures to physicians at various places on the plan of one day per week for four weeks. The cost of these courses will be borne by the state society which consists of travel expenses of lecturers.

The Committee on Postwar Planning in Massachusetts is ready to aid hospitals of the state in developing their organizations to provide approved residencies by visiting and consulting with hospital trustees and staff members. The society also plans to expand the circuit plan of graduate education which has been in operation in that state.

The 1944 Michigan State Medical Society House of Delegates created a Medical Veterans' Readjustment Program, financed by a five dollar special assessment per capita. In a few cases special and rather complicated postgraduate programs have been developed through the Office of Veterans' Affairs and the University of Michigan Department of Postgraduate Medicine.

In Missouri the Committee on Postwar Planning has prepared a preliminary report and a plea for cooperation in the plans of the national organizations which are assuming a major responsibility on a nationwide scale.

The educational program of the Medical Society of the State of New York provides for instruction consisting of single lectures, series of lectures and teaching days throughout the state in cooperation with the county medical society.

The Oklahoma State Medical Association and the State Board of Health, with funds contributed by these agencies as well as the Commonwealth Fund and the United States Public Health Service, offer a course consisting of one night a week for ten weeks in various centers throughout the state.

The Committee on Postwar Planning of the South Carolina Medical Association is preparing a program to mobilize both the medical and hospital facilities of the state in a program of education.

The Medical Society of Virginia is developing plans in order to be able to provide returning physicians with information as to where they can receive further training either of general or of specialized nature.

Tennessee has a Postwar Planning Committee which is cooperating with other agencies and institutions in the state.

The general plans of the Washington State Medical Association provide for the establishment of short clinical and some didactic courses in the various specialties. These courses will be offered primarily at King County Hospital, Seattle.

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

Fifteen examining boards leading to specialty certification have been organized, and all of these boards have been in operation since 1940. In 1933 the Council on Medical Education and Hospitals was instructed by the House of Delegates of the American Medical Association to formulate minimal standards deemed essential for certification as a specialist. At that time there were five examining boards in the medical specialties functioning: pediatrics, dermatology and syphilology, obstetrics and gynecology, ophthalmology and otolaryngology. The fifteen boards now operating are fully approved by the Council.

Two boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology and tuberculosis. Similarly the American Board of Surgery certifies specialists in proctology. Regular board certification is a prerequisite for certification in the subspecialty. This function of the boards in internal medicine and surgery is also approved by the Council.

The "Essentials of Approved Examining Boards in Medical Specialties," as prepared by the Council, outlines the type of organization and the responsibilities of such boards as well as the minimum qualifications deemed necessary for certification as a specialist. Such qualifications include graduation from an approved medical school, completion of an internship in a hospital approved by the Council, and a period of specialized training in a selected specialty. Three years of special training and a further period of two years devoted to specialty study and/or practice is considered by the Council to be the minimal training required before specialty practice. Some boards require more than this amount of training and education. Each board publishes a booklet containing information regarding its organization, personnel, purposes and requirements for certification. A statement of these requirements for each board was given in detail in the Educational Number of *THE JOURNAL* in 1942.¹ Only a few minor changes have been made by some of the boards since these regulations were published in 1942.

The Advisory Board for Medical Specialties was organized in 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada. This board reports directly to the member groups and functions in close collaboration with the Council on Medical Education and Hospitals of the American Medical Association.

The majority of the boards grant some credit for military service. The policies adopted by the boards vary. One board grants an indefinite amount of credit, to be determined by an evaluation of the experience of individual applicants. Another grants full credit for work done in the surgical division of a regularly constituted army or navy hospital. Most boards limit the credit allowed to one year of training and/or one year of experience. The special provisions for military credit made by each board were published in the 1943 Educational Number of *THE JOURNAL*.²

Prospective applicants who are in military services should obtain the booklet entitled "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" from the secretary of the board in the specialty desired. This booklet describes

TABLE 24.—Annual Specialty Board Certifications Since 1940

Year (Ended March)	Number of Boards in Existence	Number Certified That Year	Accumulated Totals
1940.....	14	15,533
1941.....	15	2,085	17,938
1942.....	15	1,756	19,694
1943.....	15	2,172	21,866
1944.....	15	1,578	23,444
1945.....	15	1,308	24,752

procedures pertaining to military credit and will enable the candidate to keep an accurate account of work done in military service duly certified and will constitute part of the credentials to be submitted on application for certification. The American Board of Internal Medicine has conducted special examinations for certification in Europe. All boards schedule examinations in various cities throughout the country throughout the year for the convenience of civilian physicians seeking certification as well as those in military service. *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* announces specialty board schedules on alternate weeks under the heading "Medical Examinations."

The 9-9-9 graduate program curtails the number of physicians desiring specialty certification. Under this wartime program the various boards are taking this into consideration and will probably allow credit for the actual time spent by the candidate in house officer training in approved hospitals.

The Council on Medical Education and Hospitals cooperates with the various specialty boards in the

1. J. A. M. A. 119:1345 (Aug. 15) 1942.

2. J. A. M. A. 122:1085 (Aug. 14) 1943.

approval of residencies and fellowships acceptable for certification. The Council inspects and evaluates new residencies in most instances; it approves residency programs jointly with the specialty boards. This program has been established so that approved services may be equally acceptable to the Council and to the respective specialty boards.

An analysis of questionnaires returned by 21,029 medical officers pertaining to their future educational plans³ indicates that over 12,000 medical officers will seek specialty certification after the war. The Council, working with specialty boards, hospitals, medical

there were 23,444 physicians certified by the fifteen boards, and in the following year 1,308 were certified. Up to March 1, 1945 a total of 24,752 certificates had been issued. Included in these figures are 764 who had been certified in the subspecialties, namely allergy 75, cardiovascular disease 325, gastroenterology 157, proctology 71 and tuberculosis 136.

In the major specialties of general medicine and general surgery, 3,541 and 2,499 respectively have received the certificate of these boards. However, the greatest number in any one specialty certified was in otolaryngology. In this specialty 3,848 have received

TABLE 25.—Approved Examining Boards in Medical Specialties

Key No.	Name of Board	Year of Incorporation	Total Certificates Awarded to		Key No.	Name of Board	Year of Incorporation	Total Certificates Awarded to

A.B. 8.	American Board of Internal Medicine..... Chairman, Reginald Fitz, 319 Longwood Ave., Boston Asst. Sec., W. A. Werrell, 1301 University Ave., Madison, Wis.	1936	3,263	3,541	Advisory Board for Medical Specialties Pres., Paul Titus, 1015 Highland Bldg., Pittsburgh Sec., Byrl R. Kirklin, 102-110 Second Ave., S. W. Rochester, Minn.				
Totals.....			23,444	24,752					

Certification in the subspecialties: By the American Board of Internal Medicine: allergy 75, cardiovascular disease 325, gastroenterology 157, tuberculosis 136, total 633. By the American Board of Surgery: proctology 71. Total certified in the subspecialties, 764. These figures are included in the above tabulation.

schools and the Committee on Postwar Medical Service, has made notable progress in meeting these educational needs of the future in the advanced training of specialists, particularly physician veterans (see discussion, pp. 55 to 57).

Table 24 gives the annual number of specialists certified by all boards for the past five years. The largest number (2,172) obtained certificates in the year ended March 1943. In the two succeeding years there were progressive decreases primarily because of the war. Of all those physicians now certified, 37 per cent received their specialty credentials in the past five years.

A list of the specialty boards and their officers and the number of certificates awarded prior to March 30, 1944 and the number certified until March 1, 1945 respectively appear in table 25. On March 30, 1944

the board's certificate since its organization in 1924. The board in ophthalmology, organized in 1917 and the oldest board in existence, has to date certified 2,437 individuals.

A key number has been assigned to each approved board, such as A.B. 1, and the biographic records of physicians published in the American Medical Directory includes by this method reference to those certified by the boards.

The Council on Medical Education and Hospitals and representatives of the various boards and the Advisory Board for Medical Specialties annually hold a joint session for the interchange of ideas and the discussion of problems of mutual interest. These meetings have proved to be worthwhile contributions to the improvement of medical education and medical practice in this country.

APPROVED MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 33 professors and 117 lecturers and instructors, a total of 150. The curriculum covers four sessions of nine months each. Entrance requirements are two years of collegiate work. The B.S. degree is conferred at the end of the second year. An accelerated program was adopted July 1, 1943, involving the admittance and graduation of a class approximately every nine months. The fees for the four years for residents of Arkansas are \$280 per year, nonresidents are charged \$225 additional each year. The registration for the present session is 266. The session began January 2 and will end September 21. The next session will begin October 1. The Dean is Byron L. Robinson, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley, Medical Center, San Francisco, Zone 22—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged, and elective chairs in homeopathic materia medica, and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. An accelerated program has been adopted consisting of three terms of sixteen weeks in each academic year. The medical course may now be completed in three years. The faculty is composed of 190 professors and 335 associates and assistants, a total of 525. The fees average \$162 per academic year, nonresidents are charged \$125 additional each year. The registration for the present session is 296. The session for the freshmen, sophomores and juniors began March 1 and will end October 20. The senior class began March 1, 1945 and will end Feb. 23, 1946. The next freshman class will begin October 29. The Dean is Francis Scott Smyth, M.D., San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS, Loma Linda, Boyle and Michigan Avenues, Los Angeles, Zone 23—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organization. Three years of collegiate work are required for admission. The faculty is composed of 43 professors and 357 associate professors, assistant professors, instructors and assistants—making a total of 400. The course covers a period of three years of four nine-month academic sessions and an additional twelve-month (nine-month for military personnel) internship in an approved hospital. The total fees are respectively, \$602, \$590, \$612 and \$620. The registration for 1944-1945 is 371, graduates 73. The present session for the freshman and sophomore students began on Dec. 31, 1944 and will end Sept. 18 and Sept. 23, 1945, respectively. The present session for the junior students began Jan. 7, 1945, and will end on Sept. 21, 1945. The last session for the senior students began on Oct. 1, 1944, and ended on July 1, 1945. The next freshman class will begin on Oct. 5, 1945. The President is Walter E. Macpherson, M.D., Los Angeles. The Dean is Newton G. Evans, M.D., Loma Linda. The Associate Dean is W. F. Norwood, Ph.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue, Zone 7—Organized in 1895 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920, reorganized in May 1928, under present title. Entrance requirements are approximately 90 semester hours. During present national emergency will operate the year round on accelerated three term basis, each term continuing for sixteen

weeks. The faculty consists of 189 professors, associate professors and assistant professors and 241 instructors, assistants and lecturers—a total of 430, 147 of whom are now on active duty with the armed forces. An internship is required for graduation. Coeducational since organization. Annual fees (1½ academic years) amount to \$852. The registration for 1944-1945 was 254, graduates 54. The last session for freshmen, sophomores and juniors began Oct. 30, 1944 and ended July 27, 1945. Seniors began their course Oct. 16, 1944 and completed the course June 23. The next freshman class will begin Aug. 6, 1945. The Dean is Burrell O. Raulston, M.D.

Stanford University-San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, University Campus, Stanford University, 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry, and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 138 professors and 190 lecturers, assistants and others, a total of 328. Two years of collegiate work are required for admission. The quarter plan is in operation. An internship is a requirement for graduation. The fees for the four years, respectively, are \$474, \$438, \$414 and \$414. The registration for 1944-1945 was 240, graduates 59. The present session for freshmen, sophomores and juniors began Jan. 8, 1945 and will end Sept. 29, 1945, for seniors Oct. 9, 1944 to June 23, 1945. The next freshman class will be enrolled Oct. 8, 1945. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The accelerated program has been adopted. The entrance requirements for nonmilitary students are three years of collegiate work. The fees average \$100 per academic year. Nonresidents are charged \$82 additional each year. The registration for 1944-1945 was 237, graduates 55. The last session began Oct. 2, 1944 and ended June 26, 1945. The present freshman class enrolled July 2, 1945. The Acting Dean is Ward Darley, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812, instruction began in 1813, first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 197 professors and 197 lecturers and assistants, a total of 394. Of this number, 29 are on leave of absence for war service and about 150 others have entered the armed forces upon completion of or during appointments. The requirements for admission are three years of collegiate work. An accelerated program has been adopted. The fees average \$506 per academic year. The registration for 1944-1945 was 250, graduates 61. The last session began Sept. 25, 1944 and ended June 16, 1945. The next freshman session will commence September 24. The Dean is Francis G. Blake, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 50 professors, 49 associate professors, 22 assistant professors, 17 adjunct professors and 155 instructors, a total of 293, of whom 71 are on military leave. The complete premedical Army Specialized Training Program or Navy College Training Program satisfied the minimum prerequisites for military or naval trainees. Civilian students must finish at least three academic years of premedical work in an approved college of

arts and sciences. The accelerated program will be continued only as long as the Army and Navy programs remain in force. The fees average \$520 per academic year. Registration for 1944-1945 was 367, graduates 87. The current session for upper classmen began July 9, 1945. The next session for first year students will begin Sept. 10, 1945. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 81 professors and 150 instructors, demonstrators and assistants, a total of 231. Sixty semester hours of collegiate work are required for admission. An accelerated program has been adopted. The fees average \$550 per academic year. The registration for 1944-1945 was 316; graduates, 73. The last session began Sept. 18, 1944 and ended in June 1945. The subsequent session for freshmen will begin Sept. 17, 1945 and end June 15, 1946; for other classes June 18, 1945 to March 9, 1946. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W. Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 38 professors and 73 instructors and assistants, a total of 111. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. An accelerated program has been adopted. The fees are, respectively, \$334, \$334, \$324 and \$331. The registration for 1944-1945 is 273. The present class began Dec. 28, 1944 and will end Sept. 7, 1945. The next session will begin Sept. 29, 1945 and end June 7, 1946. The Dean is John W. Lawlah, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street, Zone 3.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. For civilian students three years of collegiate work are required for admission. Students in the armed services are admitted in accordance with regulations set up by them. The course of study is four academic years of thirty-two weeks each. An accelerated program has been adopted. The fees for each of the four academic years are \$500. The registration for 1944-1945 was 248; graduates, 56. The last session began Oct. 2, 1944 and ended in June 1945. The next session for freshman will begin Sept. 24 and end June 15, 1946; for other classes sessions begin July 2 and end March 19, 1946. The Acting Dean is Eugene A. Stead, Jr., M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 30 professors and 65 associate and assistant professors, instructors, lecturers and assistants, a total of 95. Of this number 21 are on military leave. Three years of collegiate work are required for admission (except for the duration of the present war the minimum requirement will be two years for Army and Navy students). An accelerated program has been adopted. The fees average \$225 per academic year for residents of Georgia; nonresidents \$445. The registration for the 1944-1945 session was 285; graduates 64. The last session began Sept. 27, 1944 and ended June 11, 1945. The present session for the upper classes began July 6, 1945; the first year class will begin on Sept. 27, 1945. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue.—Organized in 1915 by acquisition of Bennett Medical College, which had been organized in 1869. Facilities enlarged upon by acquisition of Chicago College of Medicine and Surgery, faculties in basic medical sciences put on full time basis and present title assumed in 1917. Operated as an organic part of Loyola University. Coeducational since organization. The faculty is composed of 19 full time professors and 329 associate and

assistant professors, associates, instructors and assistants, a total of 348. Sixty semester hours of collegiate work are required for admission. The fees average \$515 per academic year. The registration for 1944-1945 was 313, graduates 80. The last session began on Oct. 2, 1944 and ended June 23, 1945. The subsequent session began July 5, 1945 for sophomores, juniors and seniors, and will begin on Oct. 1, 1945 for freshmen. The Dean is Italo F. Volini, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 27 professors, 147 associate and assistant professors and 446 associates, instructors and clinical assistants, a total of 620. For the duration of the war the requirement for admission is two years of collegiate work. The B.S. in medicine degree may be conferred before the end of the senior year. An accelerated program has been adopted. A hospital internship is required for graduation. The total fees are \$500 each year. The registration for 1944-1945 was 584; graduates 165. The last session began Sept. 27, 1944 and ended June 9, 1945. The present session began on June 27, 1945 for sophomores, juniors and seniors; and will begin on Oct. 1, 1945 for freshmen. The Dean is J. Roscoe Miller, M.D.

UNIVERSITY OF CHICAGO, THE SCHOOL OF MEDICINE, Fifty-Eighth Street and Ellis Avenue.—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Biological Sciences Division. The work of the first two years in the medical courses has been given on the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. The faculty of the School of Medicine is composed of 90 professors, 125 associates, instructors and others, a total of 215. The requirements for admission are 90 semester hours of collegiate work or completion of the Army or Navy premedical program. The B.S. degree may be obtained during the second year. The curriculum covers twelve quarters of work. Sixty-five students are admitted to the first year class each year. The tuition fee averages \$555. The registration for 1944-1945 was 252; graduates 62. Quarters begin in March, June, September and December of each year. All correspondence relating to general policies should be addressed to A. C. Bachmeyer, M.D., Associate Dean of the Biology Division, and that pertaining to student affairs to F. J. Mullin, Ph.D., Assistant Dean of Students.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1853 West Polk Street, Zone 12.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June 1912, and was restored in March 1913, when the present title was assumed. The staff of the Rush Medical College was incorporated in the University of Illinois College of Medicine in 1942 and at the same time Presbyterian Hospital, Chicago, became a teaching unit of the university. Coeducational since 1898. Two years of collegiate work are required for admission. An accelerated program has been adopted. The B.S. in medicine degree is conferred at the end of the second year. The faculty is composed of 250 professors and 250 associates, instructors and assistants, a total of 500. The fees for residents of Illinois average \$288 per academic year; nonresidents pay an addition fee of \$150. The registration for the present session is 665. The session began January 2 and will end September 14. The subsequent session will begin October 1, and end June 21, 1946. The Dean is Raymond B. Allen, M.D.

INDIANA

Bloomington-Indianapolis

Indiana University School of Medicine, Bloomington; 1040 West Michigan Street, Indianapolis.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The B.S. degree in anatomy and physiology is conferred. The school has been on an all time program since May 11, 1942. Three years of college work are required in normal times for admission, but during the national emergency the application from any student who has had two years of college will be accepted if his work is of a high standard. Each calendar year is divided into three semesters. The work given in two semesters is equivalent to the work formerly given in a year. The work of the first two semesters is given

at Bloomington, the remainder of the work at Indianapolis Regular fee for two semesters of work is \$217 for residents of Indiana and \$422 for nonresidents The registration for the last session was 397 The session began Dec 28, 1944 and ended Aug 18, 1945 The subsequent session will begin September 3 and will end April 23, 1946 The Dean is Willis D Gatch, M D, Indianapolis

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus—Organized in 1869 First session began in 1870 First class graduated in 1871 Absorbed Drake University College of Medicine in 1913 Coeducational since 1870 The faculty is made up of 56 professors, 74 lecturers, demonstrators and assistants, a total of 130 Three years of collegiate work are required for admission The BA degree in the combined course of liberal arts and medicine is conferred An accelerated program has been adopted The tuition fee is \$226 each year for residents of Iowa and \$490 for nonresidents The registration for 1944-1945 was 307, graduates 81 The last session began on Oct 2, 1944 and ended June 16, 1945 The present session began on July 2, 1945 for sophomores, juniors and seniors, and will begin on Sept 24, 1945 for freshmen The Dean is Ewen Murchison MacEwen, M D

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE, Lawrence, 39th Street and Rainbow Boulevard Kansas City—Organized in 1880 It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897 Absorbed Kansas Medical College in 1913 The first class graduated in 1906 The clinical courses are given at Kansas City Coeducational since 1880 The faculty includes 64 professors and 125 instructors, assistants and others, a total of 189 The requirement for admission is three years of collegiate work Students must have collegiate degree to enter sophomore year The BS degree in medicine is conferred at the end of the second year An accelerated program has been adopted The annual fees for residents of the state average \$218, nonresidents \$290 The registration for 1944-1945 was 302, graduates 80 The last session began on Oct 30, 1944 and ended June 26, 1945 The subsequent session began on July 2, 1945 for sophomores, juniors and seniors, and will begin on Sept 17, 1945 for freshmen The Dean is Harry R Wahl, M D, Kansas City

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street Zone 2—Organized in 1837 as Louisville Medical Institute The first class graduated in 1838, and a class graduated each subsequent year except 1863 In 1846 the name was changed to University of Louisville Medical Department In 1907 it absorbed the Kentucky University Medical Department, in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine In 1922 it changed its name to the University of Louisville School of Medicine Coeducational since organization Two years of collegiate work are the minimum requirements for admission Preference is given applicants with a degree or three college years leading to a degree The faculty numbers 68 professors and 70 assistants, instructors and others a total of 138 An accelerated program has been adopted Fees are \$450 for residents of Louisville and Jefferson County and \$550 for nonresidents, per school year The registration for 1944-1945 was 365, graduates 87 The last session began on Sept 27, 1944 and ended June 15, 1945 The subsequent session began July 11, 1945 and will end March 23, 1946 The Dean is John Walker Moore, M D

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE, 1542 Tulane Avenue, Zone 13—Organized January 1931 as Louisiana State University Medical Center Present title in 1939 Coeducational First session October 1931, with students of first and third year Faculty comprises 26 professors and 72 associate professors, assistant professors, instructors and assistants a total of 98 Course covers four sessions of not less than 32 weeks each Under the accelerated program adopted for the duration of the war, a first year class will be admitted each year and the entire course will be completed within a period of three years from the date of admission A minimum of three years collegiate work is required for admission Total fees, \$134 each year for residents of Louisiana, additional tuition of \$400 each year for nonresidents The registration for 1944-1945 was 325, graduates 80 The last session began Sept 27, 1944 and ended June 9, 1945 The present session began June 28, 1945 for second, third and fourth year students, and will begin Sept 13, 1945 for first

year students It will end March 9, 1946 for the first group and May 25, 1946 for freshmen The subsequent session will begin in April 1946 for third and fourth year students, June for second year students and September for first year students The Dean is Wilbur C Smith, M D

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE 1430 Tulane Avenue—Organized in 1834 as the Medical College of Louisiana Classes were graduated in 1835 and in all subsequent years except 1863 1865, inclusive It became the Medical Department of the Tulane University of Louisiana in 1884 Present title in 1913 Coeducational since 1915 The faculty comprises 34 professors and 240 associate and assistant professors, instructors and assistants, a total of 274 An accelerated program has been adopted A minimum of three years of collegiate work is required for admission Total fees average \$547 per academic year The registration for the last session was 514 The session began on Dec 1, 1944 and ended Aug 14, 1945 The next session will begin Sept 1, 1945 and will end May 15, 1946 The Dean is Hiram W Kost maver, M D

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE, 710 North Washington Street—The nucleus of a Medical Faculty was constituted in 1883 Systematic postgraduate instruction in pathology and bacteriology was begun in 1886 School was fully organized and opened in 1893 The first class graduated in 1897 Coeducational since organization The faculty consists of 71 professors and 403 instructors, assistants and others, a total of 474 The requirement for admission is temporarily two college years An accelerated program has been adopted The fees average \$627 per academic year The registration for 1944-1945 was 309, graduates 81 The last session began on Sept 25, 1944 and ended June 7, 1945 The subsequent session began June 8, 1945 for sophomores, juniors and seniors and will begin Sept 10, 1945 for freshmen The Dean is Alan M Chesnev, M D

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS, Lombard and Greene Streets, Zone 1—Organized in 1807 as the College of Medicine of Maryland The first class graduated in 1810 In 1812 it became the University of Maryland School of Medicine Baltimore Medical College was merged with it in 1913 In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed Coeducational since 1918 The faculty consists of 52 professors and 332 associate and assistant professors and others, a total of 384, of which 137 are now absent serving with the Armed Forces Premedical college training reduced from three to two years for the duration of the war An accelerated program has been adopted The tuition fees average \$508 for residents of the state, for nonresidents approximately \$150 additional The registration for 1944-1945 was 375, graduates 86 The last session began Oct 17, 1944 and ended June 22, 1945 The subsequent session for sophomores, juniors and seniors began July 19, 1945, and will begin on Sept 19, 1945 for freshmen The Dean is Robert U Patterson, M D

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street—Organized in 1873 as a homeopathic institution In 1874 the New England Female Medical College, founded in 1848, was merged into it The first class was graduated in 1874 Became nonsectarian in 1918 Coeducational since organization Army and Navy assignees are admitted on completion of the standard premedical A S T P and the V 12 programs In 1945 civilian students are being admitted on the basis of two years of collegiate training In 1946 civilian applicants will be required to present a minimum of three years of premedical work The faculty includes 23 professors, 214 associate and assistant professors, instructors and others, a total of 237 The accelerated program will be continued as long as may be required by the Army and Navy First year classes will start annually in September Total fees average \$600 per year The registration for 1944-1945 was 248, graduates 65 The last session began Oct 5, 1944 and ended June 9, 1945 The subsequent session for sophomores, juniors and seniors began June 29, 1945, freshmen will be enrolled Sept 21, 1945 The Dean is Charles F Branch M D

HARVARD MEDICAL SCHOOL, 25 Shattuck Street, Zone 15—Organized in 1782 The first class graduated in 1788 It has a faculty of 204 members, and 449 other instructors and assistants, a total of 653 Two years of collegiate work are required for admission The accelerated program has been adopted The fees average \$600, plus \$5 the first year for matriculation The registration for 1944-1945 was 525, graduates 141 The last session began Oct 2, 1944 and ended June 25, 1945 The subsequent session began on July 2, 1945 for sophomores and juniors, on June 25, 1945 for seniors, and freshmen will be enrolled Sept 24, 1945 The Dean is C Sidney Burwell, M D

TUFTS COLLEGE MEDICAL SCHOOL 416 Huntington Avenue—Organized in 1893 as the Medical Department of Tufts College The first class graduated in 1894 Coeducational since 1894 It has a faculty of 107 professors and 352 instructors, lecturers and others a total of 459 Four

academic years of college study are required for admission. An accelerated program has been adopted. The total fees for each of the four years, respectively, are \$512, \$507, \$507 and \$517. The registration for 1944-1945 was 410, graduates 97. The last session began on Oct. 2, 1944 and ended June 2, 1945. The subsequent session began in July 1945 for sophomores, juniors and seniors, and will begin on Sept. 17, 1945 for freshmen. The Acting Dean is Dwight O'Hara, MD.

MICHIGAN

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. The Dean is Edward W. Koch, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty-Eighth Street—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 277 professors and 594 instructors, demonstrators and others, a total of 871. Three years of collegiate work are required for admission. During the war, the school will remain in session throughout the year and entering classes will be enrolled once a year. Fees average \$538 per academic year. The registration for 1944-1945 was 463, graduates 114. The last session began on Oct. 5, 1944 and ended June 16, 1945. The subsequent session began on July 2, 1945 for sophomores, juniors and seniors, and will begin on Oct. 4, 1945 for freshmen. The Dean is Willard C. Rappleye, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. The faculty is composed of 155 professors and 223 instructors, assistants and others, a total of 378. All students admitted are from approved colleges for premedical training. The requirement for admission is three years of college work. An accelerated program has been adopted. The fees average \$622 per academic year. The registration for 1944-1945 was 317, graduates 77. The last session began Sept. 28, 1944 and ended June 26, 1945. The subsequent session began for sophomores, juniors and seniors on July 11, 1945, and will begin on Oct. 1, 1945 for freshmen. The Dean is Joseph C. Hinsey, Ph.D.

NEW YORK MEDICAL COLLEGE, FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869, the title New York Homeopathic Medical College and Hospital in 1887, the title New York Homeopathic Medical College and Flower Hospital in 1908, the title New York Medical College and Flower Hospital in 1936, the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. Three years of college work are required for admission. An accelerated program has been adopted. It has a faculty of 97 professors and associate professors, 76 assistant professors, 305 lecturers and assistants, a total of 478. The fees average \$683 per academic year. The registration for 1944-1945 was 434, graduates 94. The last session began on Oct. 2, 1944 and ended June 12, 1945. The subsequent session began on July 23, 1945 for sophomores, juniors and seniors, and will begin on Sept. 17, 1945 for freshmen. The President and Dean is J. A. W. Hetrick, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue, Zone 16—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. Coeducational since 1919. The faculty is composed of 233 professors, associate, assistant, clinical, associate clinical and assistant clinical professors and 362 lecturers, instructors and others, a total of 595. An accelerated program has been adopted. Entrance requirements are two years of study in an approved college of arts and sciences. The fees average \$600 per academic session. UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton—Organized in 1913. Coeducational since organization. Has given the complete six year medical course since 1924. New course—three years premedical, four years medicine, one year undergraduate internship for medical degree—has been offered beginning with the session 1942-1943. The faculty includes 15 full time and 69 part time professors, instructors and assistants and others, a total of 84, of whom 18 are absent on war service. Tuition for the first and second years is \$255, for the third and fourth years \$265 and for the fifth and old sixth year \$263. The registration for 1944-1945 was 143; graduates 33. The next session (regular) will open on Sept 17, 1945 for the first, second and third year— and on Oct 1, 1945 (accelerated) for the fifth year. The Dean is Allan C Rankin, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Bannatyne Avenue, Winnipeg—Organized in 1883 as Manitoba Medical College, first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 36 professors and 103 instructors and assistants, a total of 139. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. An accelerated program was adopted but was discontinued with class entering in fall of 1943. The course extends over four years of eight months each and a hospital internship. The fees average \$254 yearly. The registration for 1944-1945 was 183, graduates 55. The next session for the first four years will begin on Sept 14, 1946, the fifth year began on July 16, 1945. The Dean is A T Mathers M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Morris Street Halifax—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 45 professors and 36 demonstrators, lecturers and others, a total of 81, 14 of whom are in active service, and are on leave for the duration. Requires for matriculation two years of arts. The regular

medical course covers four years and a hospital internship of one year. Beginning in 1942 the last three years of the medical course were given under the accelerated plan. The final year internship was reduced to eight months. On Jan 6, 1944, Faculty decided to discontinue acceleration. The fees average \$317 yearly; \$250 additional registration fee payable by students outside the British Empire. The registration for 1944-1945 was 121, graduates 44. The next session for all classes will begin Sept 12, 1945. The Dean is H G Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston—Organized 1854. First class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 62. Fees for the first year amount to \$243, and for the following years \$255. The course consists of five sessions of 30 teaching weeks, and a sixth year spent in a hospital designated by the University. The degrees of M.D., C.M. are not awarded until the end of the sixth year. The accelerated program has been abandoned, and the pre war time table has been resumed. Freshmen will be admitted annually. Registration for 1944-1945 was 224, graduates 43. The last session for freshmen began Sept 25, 1944 and ended May 5, 1945. The next session will open on Oct 1, 1945. The last convocation was held on Feb 15, 1945, and another class will graduate in February 1946. The Dean is G Spencer Melvin, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Ottawa Avenue London—Organized in 1881 as the Western University Faculty of Medicine, first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 101. The normal course of study covers two college years of nine months each and four years of ten months each in the Faculty of Medicine. The total fees to residents of Canada for the last four years respectively are \$356, \$356, \$360 and \$360, nonresidents are charged \$646, \$646, \$650 and \$650 for each of the last four years. The registration for 1944-1945 was 204, graduates 31. The last session for freshmen began Sept 25, 1944 and ended May 5, 1945. The next session begins for all years except the first and fifth years Sept 10, 1945, and ends June 15, 1946. The Dean is G E Hall, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto 5—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 82 professors and 314 (including 87 on leave of absence for the duration of the war) lecturers, associates and others, a total of 396. The fees are \$240 for the first year, for the second \$315, \$315 for the third year, \$340 for the fourth and fifth years and \$368 for the sixth year. The registration for 1944-1945 was 657, graduates 119. The last freshman class began Sept 26, 1944 and ended May 12, 1945. The next first year class will begin the first premedical year on Sept 25, 1945, to be followed by the second premedical year in 1946-1947. The first, second, third and fourth medical years will begin on Sept 10, 1945 and end on June 1, 1946. Students in the final year graduated Feb 16, 1945. Students will graduate annually in June thereafter. The Dean is W E Galtie, M.D.

Quebec

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal—Founded in 1823 as Montreal Medical Institution, became the Medical Faculty of McGill University in 1829, first class graduated under the university auspices in 1833. No session between 1836-1939 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work are required for admission. The faculty consists of 90 professors and 162 lecturers and others a total of 252. The total fees for each of the four medical years are \$391 plus \$100 for non-British subjects. The registration for 1944-1945 was 314, graduates 91. The next session will begin Sept 5, 1945 and will end June 1, 1946. The Dean is J C Meakins, M.D.

UNIVERSITY OF MONTREAL FACULTY OF MEDICINE, 2900 Mount Royal Boulevard, Montreal—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891 by Act of Parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 200. The requirements for admission are: First, a B.A. degree (or its equivalent), second, one year premedical in the faculty of pure sciences (or an entrance examination on the premedical subjects). An internship is required for graduation. The fees average \$250 yearly. The registration for 1944-1945 was 307, graduates 56. The next freshman session will begin Sept 15, 1945 and end in June 1946. The Dean is Edmond Dube, M.D.

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 93. The fees for each of the medical years are \$200 for residents of Canada. Nonresidents are charged an extra fee of \$200 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1944-1945 was 402, graduates 37. The next session will begin Sept 14, 1945 and will end in May 1946. The Dean is Charles Vézina, M.D.

APPROVED SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

Birmingham

MEDICAL COLLEGE OF ALABAMA—Established in 1943 as a division of the University of Alabama. Located in Birmingham in 1944. Approved for military trainees. In 1945 assumed title to Jefferson Hospital and Hillman Hospital, Birmingham, Alabama. The Medical College of Alabama cares for all indigent patients of the county and city, maintenance of which is paid to the University on a per diem basis by the County. In 1943 appropriation included one million dollars for the building of a new medical school which will be erected as early as possible after the war, and temporary quarters are now in the Jefferson and Hillman Hospitals. First instruction in The Medical College of Alabama started June 4, 1945, with junior class. On Oct 8, 1945, the School of the Basic Medical Sciences on the University Campus, established in 1920, and its faculty will be absorbed into the new Medical College of Alabama. The medical college is coeducational. Minimum entrance requirements for civilian students are three years of college work. The accelerated program started June 8, 1942, and deceleration begins in 1945 with the first freshman class. The faculty of The Medical College of Alabama at this time includes seventy three professors, instructors, assistants and others, of whom seven are absent in the armed forces. The Dean is Roy Rachford Kracke, M D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE—Organized in 1903. Coeducational since organization. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. An accelerated program has been adopted. Entrance requirement is three years of collegiate work or ninety semester hours of credit. The faculty includes 9 professors, 2 assistant professors, 1 adjunct professor, 17 instructors, assistants and others, a total of 29. The total fees for the first year are \$375, and for the second year \$348. The registration for the present session is 58. The session began on Jan 29, 1945 and will end Sept 19, 1945. The next session will begin on Sept 25, 1945 and will end May 25, 1946. The Acting Dean is B S Guyton, M D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE—Organized at St Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. An accelerated program has been adopted. The faculty includes 26 professors and 12 instructors, lecturers and others, a total of 38. The entrance requirements are sixty semester hours of collegiate work. The BS degree in medicine is conferred at the end of the second year. Total fees for the first year are \$266, for the second, \$224. The registration for 1944-1945 was 75. The last session began on Sept 16, 1944 and ended June 6, 1945. The subsequent session for sophomores began on June 9, 1945, and will begin on Sept 22, 1945 for freshmen. The Dean is Dudley S Conley, M D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL—Organized by Dr Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 22 professors and 14 instructors, a total of 36. Army or Navy premedical curricula accepted for admission. An accelerated program has been adopted. Candidates for the AB degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1944-1945 was 45. The present session began on March 5, 1945 and will end Oct 24, 1945. The subsequent session for both classes will begin Nov 5, 1945. The Dean is Rolf C Syvertsen, M D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910 when the clinical department at Raleigh was discontinued. Coeducational since

1914. Three years of college work are normally required for admission. Certificates are awarded on the completion of two years' work in medicine. The faculty is composed of 20 professors, 13 instructors, and 10 lecturers, a total of 43. The fees for each year are \$298 for the first year and \$323 for the second year for residents; for non residents an additional fee of \$100 per year. The registration for 1944-1945 was 99. The last session began on Sept 18, 1944 and ended June 9, 1945. The subsequent session for sophomores began on June 18, 1945, freshmen will be enrolled Sept 17, 1945. The Dean is W Reece Berryhill, M D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years work in a college of liberal arts are required for admission. (For the duration of the war about two years as per Army and Navy plans.) The BS degree in combined arts-medical course is conferred at the end of the second year. The faculty consists of 7 professors and 7 instructors, a total of 14. The fees are \$170 each year for resident students and \$340 for nonresidents. The registration, academic year Jan 2, 1945 to Sept 22, 1945, is 51. The subsequent session will begin Sept 24, 1945 and end June 8, 1946. The Dean is H E French, M D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Two years work in a college of liberal arts are required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the AB degree. The BS degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) AB degree. The faculty numbers 18. An accelerated program has been adopted. The tuition is \$150 each year for residents and \$255 for nonresidents. The registration for 1944-1945 was 48. The last session began Sept 11, 1944 and ended June 3, 1945. The subsequent session for sophomores began June 11, 1945, freshmen will enroll on Sept 17, 1945. The Dean is Joseph C Ohlmacher, M D.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE—Organized in 1902, gives the first two years of the medical course, but agreement has been made for the transfer of 20 students each year to the Medical College of Virginia. Coeducational since organization. Entrance requirements are three years of collegiate work. The BS degree in medicine is conferred at the end of the second year. An accelerated program has been adopted. Faculty numbers 24. Fees for residents of the state are, respectively, \$255 and \$265, nonresidents, \$150 additional each year. The registration for 1944-1945 was 55. The last session began Sept 25, 1944 and ended June 16, 1945. The subsequent session begins for freshmen Sept 24, 1945 and sophomores began their work on June 25, 1945. The Dean is Edward J Van Liere, M D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon—Organized in 1926. Coeducational. Offers the first two years of the medical course. An accelerated program has been adopted. Two years of collegiate work are required for admission. The BA degree is conferred at the end of the second year. The medical faculty includes 8 professors and 7 lecturers and assistants, a total of 15. The fees are \$150 for the first year and \$200 for the second year. The registration for 1944-1945 was 49. The last session for freshman began Oct. 10, 1944 and ended May 11, 1945, for sophomores May 30 to Dec 22, 1944. The next session for freshmen and sophomores will begin Oct 1, 1945 and Sept 10, 1945 respectively. The Dean is W S Lindsay, M B.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

SATURDAY, SEPTEMBER 1, 1945

THE EDUCATIONAL NUMBER, 1945

This forty-fifth annual Educational Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION presents data on the last wartime year in medical education, although the effects of the war will still be felt for a long time. All but ten schools have now completed the cycle of four graduating classes in three calendar years. During these three years there have been 20,662 graduates in the United States, which is 5,127 more than in the three years preceding the war.

This contribution of medical schools to the war is especially noteworthy, since it came at a time when faculties were depleted in numbers and the demands on the time and energy of those remaining were excessive.

The statistics and information contained in this Educational Number of THE JOURNAL are a continuation of this valuable annual service of the Council on Medical Education and Hospitals of the American Medical Association. Many groups, agencies, institutions and individuals have contributed to this compilation. Sincere thanks are due them, not only from the Council and THE JOURNAL, but from the many thousands of people interested in medicine and medical education who find this publication useful.

NEW MEDICAL SCHOOLS

The past year has seen the expansion of the University of Alabama School of Medicine from the two year to the four year status, and the formulation of plans and the appropriation of funds for a new medical school by the University of Washington in Seattle. Progress thus far seems to promise well for the success of both programs.

Considerably less may be said of the prospects of some of the other proposed ventures into the extremely costly field of medical education. Every state operating a school of the basic medical sciences is now considering expansion to a full four year medical school course. Some of the reasons given for such programs are not always sound. They include the following: Great num-

bers of physicians are away on military duty. New schools are required to supply the overall increase of physicians needed in this country after the war. Rural areas have too few physicians. None of these is an adequate reason for attempting to establish new medical schools.

Too often the proposals fail to recognize that medical education is the most expensive form of professional training; that a four year medical school costs far more to operate than a school of basic medical sciences; that there is a strong trend toward the employment of full time clinical instructors; that a physician needs teaching experience and training in addition to his M.D. degree to qualify as a teacher, even in clinical fields; that medical school hospitals must be specially designed and equipped; that medical schools must carry out research; finally, that medical schools must be so located as to insure an adequate supply of patients and of teachers, including specialists.

This kind of faulty thinking and lack of knowledge about medical education can only lead to costly and futile ventures which fail to reach the desired ends.

THE SUPPLY OF MEDICAL STUDENTS

Before the war ended, it was generally known that there would be a deficiency in numbers or quality of the men enrolled in freshmen medical classes in the near future, because exceedingly few able bodied men have been permitted to carry on premedical studies. The ending of the war has not changed this situation; it merely permits an estimate of the duration of deficient enrolments. If inductions are stopped in time for large numbers of medical students to enroll in the fall college sessions—which seems unlikely—there may be an approximation to the normal number of qualified medical school applicants in 1947. This may not come until 1948, since there must be added to the one lost premedical year still another year, because of the general shift from the two year to the three year requirement for admission.

Most medical schools are returning to annual admissions, even though acceleration will be continued after admission, at least as long as there are military students in the schools. When and how the A. S. T. and Navy V-12 medical programs will be discontinued has not been announced. Unless there is coordination between the Army and Navy and unless the medical schools are consulted through the liaison committee of the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges, a great deal of needless confusion is certain to result in this process.

Another factor is the rate of demobilization. Every indication is that this cannot be sufficiently rapid to return many qualified premedical students to their civilian studies until late winter or spring unless a special

adjustment is made. The Vannevar Bush report to the President recommends that qualified premedical (and other science) students "be ordered, by name, to duty in the United States as students." This plan "should be adopted as the considered policy of the armed forces, and no desire of a commanding officer . . . should be allowed to interfere with the operation of the policy." Such assignment "would be no disruption of plans for the discharge of soldiers . . ." because, in the course of the assignment to premedical studies on active duty, the discharge of such students "would occur in accordance with the already established rating scale."

Mr. Paul V. McNutt, chairman of the War Manpower Commission, announces a federal program with an immediate goal of the registration of qualified veterans in medical and premedical schools for courses starting this fall. Provided the veterans are selected by the medical schools, this program is in keeping with the objectives of the Council on Medical Education and Hospitals of the American Medical Association to encourage the development of adequately trained physicians to the end that the country will be satisfactorily supplied with medical service.

Mr. McNutt's release properly emphasizes the point that veterans must be suitably equipped with educational and other prerequisites to become future physicians; the number of medical students which can be accepted in any one year is also conditioned by the facilities available.

With the war now over, such replacements as are still needed for the armed services can well come from inductees not qualified to prepare for medical and scientific careers, and men on duty who should undertake such studies ought to be returned at the earliest moment.

PREVENTION OF PELLAGRA

Casal in 1735 argued that pellagra was due to some toxic or infectious factor in corn. Then in 1925 Goldberger¹ reported evidence that the disease is presumably due to inadequate amounts of some essential nutritional factor in corn. Elvehjem and his associates² afterward isolated this essential factor and identified it as nicotinic acid. In confirmation of the Goldberger theory nicotinic acid was afterward found to be clinically effective against blacktongue in dogs and against many (but not all) pellagra symptoms in man.

As analytic methods were perfected, the deficiency theory was challenged. On a dry weight basis corn contains as much nicotinic acid as eggs, milk, polished rice, oats or rye, and often more. The presence of an unknown pellagra producing toxin in corn was thus indicated. In confirmation of this toxic theory Handler³

of Duke University found that the blacktongue syndrome in dogs is more readily produced on diets containing corn than with purified rations which contain much less nicotinic acid. Krehl and his associates⁴ of the University of Wisconsin afterward noted that corn exerts a pronounced retardation of growth in rats which is counteracted by nicotinic acid. Polished rice or rolled oats, both of which contain significantly less nicotinic acid than corn, did not produce depression of growth when fed under identical conditions.

In order to determine the mechanism of this depression of growth, Krehl⁵ made careful studies of the effects of corn grits on the nicotinic acid requirements of dogs. The experiments were conducted with growing dogs which had been kept since weaning on a synthetic diet low in nicotinic acid. Corn grits were incorporated in the synthetic ration at a level of 60 per cent at the expense of sucrose. Enough nicotinic acid was then added to adjust the level to 2 mg. per hundred cubic centimeters for one group of dogs and to 5 mg. per hundred cubic centimeters for a second group. Based on a daily consumption of 35 Gm. per kilogram, the two groups received each day 0.42 and 1.05 mg. of nicotinic acid per kilogram of body weight. The lower figure was at least 25 per cent higher than the minimum nicotinic acid requirement for growing dogs.⁶

By the end of fifty-one days the average growth of the dogs on the higher level of nicotinic acid was 77 Gm. per day. For the group at the lower nicotinic acid level the average daily growth was 37 Gm. In a control group of dogs fed a ration containing only 36 per cent corn grits the growth rate averaged 65 Gm. per day at the lower level. This was quite comparable to the 77 Gm. daily average with dogs maintained at the higher (luxury) level of nicotinic acid.

From these and similar data Krehl concludes that corn significantly increases the nicotinic acid requirement of growing dogs. The simplest explanation of this effect would be to assume that corn contains some relatively indigestible substance (or factor) which combines with dietary nicotinic acid so as to prevent its absorption from the digestive tract. This would be in line with the known effects of charcoal, liquid petrolatum and egg white. "Avidin," the undigestible factor in egg white, has a specific affinity for biotin. Fed in sufficiently large amounts, "avidin" causes lethal biotin starvation. Other more complex theories of the antivitamin effects of corn are suggested by the known synthesis or destruction of nicotinic acid by the intestinal flora. While corn tends to increase the nicotinic acid requirement of dogs, Krehl found that other foods, such as milk, casein and glucose, which contain much

less nicotinic acid, tend to decrease this requirement. Krehl believes that this reduced nicotinic acid requirement is due to the establishment of an adequate nicotinic acid synthesizing intestinal flora.

Summarizing his results, Krehl concludes that on a heavy corn grit diet the nicotinic acid requirements of man are probably at least three times the requirements for comparable growth on a synthetic diet or whole milk ration. From this he suggests that the enrichment of corn meal and other milled corn products should be increased to include considerably more nicotinic acid than is at present thought necessary. Krehl's data also suggest that the same prophylactic effects could be obtained by increasing the amount of milk or milk products in daily human diets.

VITAMIN IMBALANCE

With the introduction of pure vitamins, particularly members of the B complex, interest in the possibility of interrelation of vitamin activity has been stimulated. In the clinical literature are suggestions of the possible interrelation or antagonism of some of the B vitamins. Pellagrins often show symptoms of thiamine or riboflavin deficiency after receiving nicotinic acid; the added niacin may either increase the thiamine or riboflavin requirement of the pellagrin or actually antagonize the effect of the small amounts of the other B vitamins present. In addition, the possibility of producing an improper balance of vitamins should also be considered. This may now be easy to achieve, since there are many pure preparations of vitamins available allowing for the administration of unphysiologic doses of a given vitamin.

Early attempts to produce a deficiency of one of the B vitamins by overdosing with other members of the complex have not met with much success. Recently Richards¹ has demonstrated that overloading the diets of rats on a diet low in vitamin B₆, pyridoxine, with large amounts of thiamine caused vitamin imbalance, with the consequent production of symptoms of pyridoxine deficiency—seizures of epileptiform nature which made its diagnosis relatively simple. Other investigators have shown that these symptoms are present in young rats nursed by mothers that consumed a ration poor in pyridoxine. By the administration of pyridoxine to the mother after parturition, the seizures could be prevented in the young. The work illustrates strikingly that a pyridoxine deficiency is caused in rats by feeding large doses of thiamine. The possibility of the antagonism of other B factors by excess of thiamine may exist, but the symptoms of pyridoxine deficiency overshadowed other possible deficiency signs.

Najjar and Holt² have shown that there is a fluorescent substance in the urine of normal subjects but lacking in the urine of pellagrous patients. Later Najjar

and his associates³ showed that the fluorescent factor appeared to be a derivative of nicotinamide, the butyl ether of N-methylnicotinamide alpha carbinol. Thus the amount of fluorescent material in the urine parallels the amount of nicotinamide or nicotinic acid in the urine. Recently Singal, Hall and Sydenstricker⁴ observed that the amount of fluorescent substance in the urine was increased by the administration of pyridoxine to normal dogs and to those maintained on a diet deficient in niacin. This signifies that the amount of nicotinic acid in the urine is increased. The administration of large doses of pyridoxine also increased the severity of the nicotinic acid deficiency.

With more knowledge of the interactions of vitamins, the possibility of vitamin imbalance must be considered. Indiscriminate administration of large amounts of individual members of the B complex, particularly thiamine, may lead to other vitamin deficiencies. The addition of vitamins as in the fortification of foods should also be considered in regard to the possibility of vitamin imbalance. Balancing of the vitamins may be of considerable clinical importance, particularly in diets of those in low economic levels or in the highly restricted diets of food faddists or patients with allergy.

Current Comment

CHILD SPACING AND STILLBIRTHS

Eastman¹ recently suggested that youth is a better ally than child spacing to the health of the mother and her child. This conclusion was based on an analysis of over 5,000 Baltimore births. Now, however, Yerushalmy,² who has made a statistical study of more than 7 million births, comes to a different conclusion. He found that the lowest stillbirth rates do not occur among the youngest mothers where "youth" might be expected to be the dominant factor. The rate is relatively high for mothers between the ages of 15 and 19 years (33.7) and drops to 23.3 for mothers between 20 and 24, increasing thereafter with the age of the mother to 56.2 in the 40 to 44 age bracket. The rate of stillbirths varies also according to the number of children born: there is a definitely lowered stillbirth rate for the sixth child of a mother aged 30 than for the sixth child of a mother aged 20. The eighth child born to a woman by the time she is 25 has a much higher stillbirth rate than a fourth child born to a woman the same age. Yerushalmy did not determine how much time should elapse between the birth of one baby and the beginning of another pregnancy by women of different ages and number of children. However, his observations emphasize that a period of rest and recuperation is essential to the average woman and that babies born either too close

2. Najjar, V. A., and Holt, L. E., Jr.: *Science* 93: 20 (Jan. 3) 1941.

together or at too wide intervals have less chance of being born alive than those spaced at moderate intervals. Furthermore, Yerushalmy concludes that the interval between births is a basic factor in the incidence of stillbirth. Although at first glance the Eastman and Yerushalmy studies appear to give conflicting results, it is not certain that they cannot be reconciled. Probably the age of the mother, child spacing and total number of children would all influence not only the incidence of stillbirths but also the maternal health.

RESIDENCIES FOR PHYSICIAN VETERANS

For many months the Committee on Postwar Medical Service and the various American boards in the specialties have been working with the Council on Medical Education and Hospitals of the American Medical Association to provide additional residency places of high quality for returning veterans seeking such work. At present there are nearly two thousand places available in excess of those open in 1943. These have already been approved by the Council, after inspection of the facilities, and are acceptable to the American boards. They will go a long way toward meeting the increased postwar demand for advanced hospital training. Many more hundreds of openings will be available by the time the peak of demobilization is reached. There is every indication that hospitals and medical schools will meet the educational needs at this level. There still remains the necessity for the organization of more full time courses of three months' duration of these two kinds: a general review of the major fields of clinical medicine for the general practitioner and review courses in the various specialties for physicians whose interests are primarily in one field and who wish a refresher course to bring them up to date.

EXAMINATION OF AIRPLANE PILOTS

Experience in the medicine of aviation in the United States before the war led experts who are members of the Aero Medical Association and of the medical division of the Civil Aeronautics Administration to establish high standards of qualification for the examination of airplane pilots. On June 1 the Civil Aeronautics Administration cut the examination of private and student pilots to a minimum. Previously only qualified examiners were permitted to make such examinations. Now the examinations may be made not only by general practitioners but even by osteopaths who happen to be licensed to practice medicine in any of the states. This reversal of policy is so fraught with danger to the flying public and to the millions of persons who will be hazarding their lives in flight in the postwar period that experienced examiners now qualified particularly in this field threaten to discontinue their connection with the CAA. The Congress of the United States has placed on the CAA the duty of regulating and controlling aviation so as to "assure the highest degree of safety." By this backward step a federal agency is apparently permitting selfish and political pressures to force on it a disregard of the high obligation committed to it by the Congress.

THE MEDICAL SCHOOL CURRICULUM

The present time is most propitious for serious curriculum revision. In recent years virtually no changes have been made by most schools except for the unstudied addition of required hours, which is the easiest and least rational kind of change. The medical school curriculum should be completely overhauled, bearing in mind the almost universal need for reducing the didactic assignments throughout the four years, allowing students free time for special interests, reducing the mass of detail required of students, integrating the work of the various departments intelligently, utilizing the case method of clinical instruction more extensively, elevating the clinical student to a position of dignity above that of a school boy, instilling in students an impelling curiosity about the unknown and incorporating studies of medical economics and the distribution of medical care into medical education. Unless progress is made along these lines, medical education will continue to lag far behind the advances which have been made in general education in recent years.

CELLULAR PATHOLOGY

Paul Klemperer¹ reviews briefly in a recent article the results of certain investigations in cellular pathology. As yet results of immediate practical value have not come from the study of the intracellular network known as the Golgi apparatus. It seems clear, however, that this apparatus is definitely related to the functions of exocrine as well as endocrine gland cells in that its size increases in the course of their secretory activity. More strikingly significant is the disappearance of the granules in the B cells of the islands of Langerhans in experimental alloxan diabetes. The outcome of the study of the granules in the human pancreas under various conditions will be of much interest. The demonstration of the changes in the cells of the hypophysis on removal of other endocrine glands or on hormonal injection is a second example of morphologic study in experimental endocrinology. Klemperer next turns attention to the juxtaglomerular neuromyoarterial apparatus, composed of epithelioid cells, concerning the function of which, whether secretory or regulatory, there is difference of opinion. The visual demonstration of intracellular enzyme activity is another phase of cell morphology. Mention may be made only of the results bearing on the formation of pigment in the body and on phosphatase activity of certain cells. In respect to the latter, further study of human material promises valuable results. Of the structural changes in avitaminosis Klemperer discusses the keratinizing metaplasia in vitamin A deficiency and the failure of connective tissues to produce and keep up intercellular substances in vitamin C deficiency. This effect of C deficiency is of great interest in relation to the alterations in the connective tissue in acute rheumatic fever, disseminated lupus and scleroderma. This review, though limited to particular lines of work, illustrates well the importance that cellular pathology maintains in medical science.

MEDICINE AND THE WAR

ARMY

PLASTIC EYE CENTERS FOR ARMY MEDICAL DEPARTMENT

Thirty installations, twenty-nine general hospitals and one regional hospital, have been designated plastic eye centers for the Army Medical Department. All existing laboratories have adequate space, personnel and supplies, with the exception of one general hospital, and action is being taken to expand the facilities so that production can be increased at this establishment. Approximately 5,100 plastic artificial eyes were made and fitted up to June 30, 1945. In addition, the plastic eye laboratories have made conformers, eye spheres and other appliances for the eye clinics.

Experimental work is still being carried on in the plastic artificial eye program. Technicians are continually endeavoring to improve and give these plastic eyes greater mobility and lessen abrasion. Three teams of officers and enlisted men who are experienced in making plastic artificial eyes are overseas, and four additional teams are now being trained in this work.

AWARD OF MERITORIOUS SERVICE UNIT PLAQUE

The Meritorious Service Unit Plaque was recently awarded to the Medical Detachment, 271st Infantry Regiment, 69th Infantry Division, United States Army, "for superior performance of duty in the accomplishment of exceptionally difficult tasks from Feb. 11, 1945 to May 7, 1945 in Belgium and Germany. The Medical Detachment has demonstrated its unusual skill in coping with intricate and difficult situations. Through its brilliant professional attainment the Medical Detachment has achieved an enviable record. One thousand one hundred and fifty-five soldiers have been treated at aid stations without the occurrence of a single death. Casualties from the battlefield were evacuated in the record time of ninety-two minutes. Despite the most severe weather conditions and heavy enemy action, the Medical Detachment displayed the greatest adaptability and resourcefulness. The ability, courage and devotion to duty displayed by the Medical Detachment reflect the highest credit on this unit and the armed forces of the United States." The commanding officer of the medical detachment is Major Leo Litter, formerly of New York.

DEDICATE MADIGAN GENERAL HOSPITAL

The Madigan General Hospital, Tacoma, Wash., was recently dedicated. Formerly Fort Lewis Hospital, the Surgeon General requested on May 18, 1944 that this installation be converted to a general hospital for the medical department. Madigan General Hospital is named for Col. Patrick S. Madigan, formerly of the medical corps of the United States Army. He died May 8, 1944 while stationed at Fort Belvoir, Virginia. Colonel Madigan graduated from Georgetown University School of Medicine, Washington, D. C., in 1912 and was commissioned in the Medical Corps of the Regular Army on Oct. 21, 1917.

38th GENERAL HOSPITAL AWARDED PLAQUE

The 38th General Hospital of the Jefferson Medical College, now in Cairo, Egypt, was recently awarded the Meritorious Service plaque. The citation was made by the commanding General of the African Middle East Theater, who cited the unit for superior performance of duty in the accomplishment of exceptionally difficult tasks and for the maintenance of a high standard of discipline from January 1944 to July 1944. The 38th Hospital Unit is in command of Lieut. Col. Robert B. Nye.

ARMY AWARDS AND COMMENDATIONS

Major Francisco A. Rosete

The Bronze Star was recently awarded to Major Francisco A. Rosete, formerly of Chicago. A captain in rank during this period, and responsible for the 55,000 Filipino civilians, Major Rosete organized and supervised twenty-three dispensaries and eight hospitals in the northern Luzon sector. Because the Japanese had furnished no medicines or medical aid for these civilians during their three years of occupation, disease was rampant with various types of maladies, many of them in the last stages owing to the lack of previous attention. Major Rosete, with untiring energy and drive, obtained the necessary medicines and equipment for taking care of these diseases, and through his initiative and efforts they have been cured and are on the decline. In performing his duties he has worked long hours, tirelessly tending the bodily ills of the diseased civilians and frequently with little or no help from other trained personnel.

Besides curing diseases, part of his work has been that of prevention. He has been a crusader in cleaning up filth and breeding grounds of diseases. He has tried to educate the civilian population to maintain higher standards of sanitation and has appointed and supervised sanitary inspectors who require the civilians to improve their living conditions through this preventive measure.

"In curing and preventing diseases among the civilians, Major Rosete has reduced the danger of infection and diseases among the members of the 33d Infantry Division, because of the fraternization between the civilians and the military. In this respect he has aided the 33d Division in the accomplishment of its tactical missions," the citation read in part. Dr. Rosete graduated from Loyola University School of Medicine, Chicago, in 1938 and entered the service Aug. 26, 1942.

Captain Joseph H. Hillman

The Bronze Star was recently awarded to Capt. Joseph H. Hillman, formerly of New York, "for meritorious service in connection with military operations against the enemy as anesthesiologist, 3d Auxiliary Surgical Group, from June 7, 1944 to Nov. 17, 1944 in France, Belgium and Germany. Since his arrival on the European continent Captain Hillman has displayed marked proficiency and professional skill in the administration of innumerable anesthetics and in the improvisation of equipment which permitted the performance of major surgical operations in a division clearing station. By his demonstration of outstanding medical ability and personal initiative, Capt. Hillman reflected credit on himself and the military service." Dr. Hillman graduated from the New York University College of Medicine, New York, in 1930 and entered the service Aug. 1, 1942.

Major John Erbes

Major John Erbes, formerly of Windsor, Colo., has been the recipient of a Distinguished Service Cross, four Silver Stars and a Bronze Star. As a battalion and regimental surgeon, Major Erbes served in the heat of every major European battle from Africa to Germany with the Panzer tamer "Hell-on-Wheels" 2d Armored Division. Decorated the first time in Africa with a Silver Star for "stealing a half-track, loading it with wounded and running them to safety while Nazi tanks fired and chased us all over the desert," he established a standard pattern for himself which was to distinguish his actions in France, Belgium and Germany. The nation's second highest military award, the Distinguished Service Cross, was won for another courageous rescue near Aachen. Leading three men into an open bullet and shell scourged field where a dozen wounded lay surrounded by

Germans, Erbes bore a Red Cross flag, in accordance with Geneva conference rules. "Artillery fire continued, however," he stated, "and I was just about to dive into a hole when some guy with a machine gun cut down on me, sending bullets through the flag and chipping the staff. It furnished the impetus to really put me in that hole. After a while most of the small arms fire died down, but the artillery kept pounding." Major Erbes recruited "help from the foxholes" as litter carriers and with them made four 1,600 yard trips through the avalanche of artillery fire. Some of the men were so seriously wounded that he was forced to perform amputations with only a bandage scissors. Dr. Erbes graduated from the University of Nebraska College of Medicine, Omaha, in 1939 and entered the service July 1, 1941.

Brigadier General John A. Rogers

The Distinguished Service Medal was recently awarded to Brig. Gen. John A. Rogers, formerly of Washington, D. C. Accompanying the award was the citation "As Surgeon of the First Army in France, Belgium and Germany from June 1944 to April 1945 he demonstrated rare organizational ability and exceptional judgment in his superior handling of the First Army's medical service. Energetically pursuing the army commander's principle of placing hospitals as near the line of combat as possible, he overcame with highly ingenious methods the difficulties presented by the greatly augmented army racing across western Europe and covering an unusually extended front. In cooperation with the Air Forces and Navy he developed highly effective procedures for evacuating the wounded by aircraft and boats. Despite all obstacles he furnished to First Army casualties a medical service that was exceptional in efficiency, as shown by the low mortality rate attained. By his keen professional ability and tireless devotion to duty he contributed directly to the saving of thousands of lives and to the combat effectiveness of the First Army." Dr. Rogers graduated from Tufts College Medical School, Boston, in 1914 and has been in the service since Dec. 8, 1917.

Captain Joseph J. Healy Jr.

Capt. Joseph J. Healy Jr., formerly of Brooklyn, flight surgeon with the 417th Bomb Group "Sky Lancers," an attack bomber unit of the Fifth Air Force in the Philippines, was recently commended for aiding in the rescue of two survivors of an airplane crash. While the Sky Lancers were stationed in New Guinea, one of their A-20 Havoc bombers made a crash landing in the jungles of the interior. Captain Healy volunteered to participate in the ground rescue of the two surviving members of the crew. He and his party made their way inland to within 2 miles of the location of the crashed plane by traveling up a tropical river in a launch, after which they proceeded overland to reach the plane, which was in the middle of a sage swamp. Even with the help of numerous natives, it took two days to reach the survivors, for there were almost insurmountable barriers of waist deep swamp, a thick overgrowth of sage palms 15 to 20 feet in height, almost impenetrable undergrowth, tropical downpours, and swarms of mosquitoes. Dr. Healy graduated from the Long Island College of Medicine, Brooklyn, in 1940 and entered the service Aug. 18, 1942.

Captain John F. Schlechter

The Soldier's Medal was recently awarded to Capt. John F. Schlechter, formerly of Brooklyn. Accompanying the award was the citation "for heroism at St. Dizier, France, on Dec. 22, 1944. An A-20 aircraft skidded head on into a parked P-47 aircraft loaded with Napalm bombs, which were torn loose and lay open and exposed around the wreckage in constant danger of exploding. On noticing the navigator imprisoned and seriously injured in the nose of his ship, Captain Schlechter, heedless of his own safety, rushed in, freed the navigator, carried him to safety and administered medical attention. Captain Schlechter's intense desire to render aid, no matter at what the cost or odds to himself, reflects credit on himself and is in keeping with the highest traditions of Army Air Forces." Dr. Schlechter graduated from the New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1941 and entered the service Aug. 20, 1942.

Captain Morton H. Rose

Capt. Morton H. Rose, formerly of Washington, D. C., was recently awarded the Bronze Star "for heroic achievement in connection with military operations against the enemy on April 13, 1945 in Germany." Dr. Rose graduated from George Washington University School of Medicine, Washington, D. C., in 1942 and entered the service on March 13, 1943.

Major Pasquale P. Franzese

Major Pasquale P. Franzese, formerly of Brooklyn, was recently awarded both the Bronze Star and the Unit Citation for meritorious service against the enemy at Kiriwina, Trobriands; Cape Gloucester and Talasea, New Britain; Aitape, British New Guinea, and Wakde-Toem, Dutch New Guinea. With complete disregard for his own safety he supervised the evacuation of casualties from areas under enemy fire, thus accomplishing rapid and life-saving hospitalization of these casualties. Major Franzese served as commanding officer of medical units that saw eighteen months' continuous service in combat areas. He graduated from Long Island College of Medicine, Brooklyn, in 1939 and entered the service Feb. 21, 1941.

Captain J. H. Gosman

The Legion of Merit was recently awarded to Capt. J. H. Gosman, flight surgeon, formerly of Indianapolis, for the development of an electrical headset for the treatment of ear trouble among combat fliers. This headset has shortened the period of treatment from three to five days. He was also cited for his work in the fields of sanitation and immunization. Dr. Gosman graduated from Indiana University School of Medicine, Indianapolis, in 1938 and entered the service March 27 1941.

Captain John S. Morawski

The Bronze and Silver stars were recently awarded to Capt. John S. Morawski, formerly of Brooklyn. The Bronze Star was awarded for heroism during a ten day period in September 1944 when his battalion was under constant artillery and mortar fire. Unmindful of personal risk, Captain Morawski went to the rescue of wounded personnel despite shells falling in their vicinity. The Silver Star was awarded for gallantry in action when Captain Morawski climbed into a disabled tank and supervised the evacuation of the wounded. One soldier was badly in need of plasma, which was successfully administered by the captain despite the shell fire about him. Dr. Morawski graduated from the Long Island College of Medicine, Brooklyn, in 1942 and entered the service July 16, 1943.

Captain Edmund R. Kinne

The Bronze Star was recently awarded to Capt. Edmund R. Kinne, formerly of Middletown, N. Y., "for heroic achievement in Germany, February 9. During the assault for the initial bridgehead across the Sauer River into the Sigfried Line, Captain Kinne of the Medical Department and two enlisted men volunteered to establish an advance aid station to care for the wounded. Crossing the river in a boat they worked continuously for thirty-six hours despite heavy shell fire to sustain life in the wounded until they could be ferried across the river. While performing these duties Captain Kinne was wounded by shell fragments. Dr. Kinne graduated from the College of Medical Evangelists in 1944 and entered the service in January 1944.

Major Edgar A. Lawrence

The Air Medal was recently awarded to Major Edgar A. Lawrence, formerly of New York. According to the citation "The Air Medal is hereby awarded for meritorious achievement while participating in more than one hundred hours of combat aerial flight over territory in Burma and China where exposure to enemy ground and air fire was probable and expected. This display of devotion to duty and a degree of efficiency above and beyond that usually expected reflects credit on this officer and on the Army Air Forces of the United States." Dr. Lawrence graduated from Johns Hopkins University School of Medicine, Baltimore, in 1933 and entered the service June 1, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Commander Charles W. Letcher

The Silver Star was recently awarded to Commander Charles W. Letcher, formerly of Wilkes-Barre, Pa., for "distinguishing himself conspicuously by gallantry and intrepidity while serving as medical officer on board an aircraft carrier. His vessel was directly engaged in supporting the landing of troops in the Southwest Pacific Area, when enemy air attack caused serious battle damage to the ship. An enemy plane and bomb hit and damaged sick bay, necessitated its evacuation and seriously wounded many of the personnel. Although he was painfully wounded, he disregarded his own injury and efficiently directed the orderly evacuation. With untiring devotion to duty, he continued to direct the entire process of caring for the casualties. His own skilful medical and surgical administration unquestionably saved the lives of a number of seriously wounded and contributed to the quick recovery of many others. By his knowledge of his profession, his leadership and courage he set an inspiring example which was in keeping with the highest traditions. . . ." Dr. Letcher graduated from Jefferson Medical College of Philadelphia in 1930 and entered the service in January 1940.

Lieutenant Commander Roy Randolph Powell

The Navy and Marine Corps Medal was recently awarded to Lieut. Comdr. Roy Randolph Powell, formerly of White Plains, Va. The citation accompanying the award read "for distinguishing himself by heroism while serving as senior medical officer aboard an aircraft carrier during the action of Nov. 25, 1944. Lieut. Comdr. Powell, with flight deck fires above him and hangar deck fires below him, heroically, with disregard for his own personal safety and unselfish devotion to

duty, continued to treat casualties in the main battle dressing station, menaced by fire and suffocation, until all casualties were treated and safely removed to sick bay. His fearlessness, courage, utter disregard of his own safety and devotion to duty were at all times in keeping with the highest traditions of the United States Naval Service." Dr. Powell graduated from the University of Virginia Department of Medicine, Charlottesville, in 1935 and entered the service Jan. 16, 1937.

Lieutenant Commander Frank A. Patti

The Legion of Merit was recently awarded to Lieut. Comdr. Frank A. Patti, formerly of Leonia, N. J., "for distinguishing himself by exceptional meritorious conduct in performance of outstanding services in operations against the enemy in the battle of Leyte." Lieutenant Commander Patti is chief medical officer on the U. S. S. *Santee*. He graduated from the Long Island College of Medicine, Brooklyn, in 1931 and entered the service May 2, 1942.

Lieutenant L. Vincent Strully

Lieut. L. Vincent Strully, formerly of New York, received a commendation for outstanding devotion to duty and meritorious service in preparation for the invasion of France. "His performance was in accordance with the highest traditions of and reflects great credit on the U. S. Naval Service." Dr. Strully graduated from the Long Island College of Medicine, Brooklyn, in 1938 and entered the service July 1, 1943.

Lieutenant Glen G. Rice

The Silver Star was recently awarded to Lieut. Glen G. Rice, formerly of Seattle. Dr. Rice graduated from the University of Oregon Medical School in 1942 and entered the service July 10, 1943. He also shares in a presidential unit citation and was the recipient of the Purple Heart.

MISCELLANEOUS

QUININE BEING RELEASED FOR CIVILIAN MEDICINAL PURPOSES

The War Production Board recently announced that a limited amount of quinine is being released from the government stockpile for civilian antimalarial and other essential medicinal needs. Allocations of quinine, including the newly released quantities, will be made by WPB in accordance with the provisions of order M-131, governing cinchona bark and cinchona alkaloids. Wholesalers, distributors and processors are required to file form WPB-2945, stating the medicinal dosage form in which the quinine will be sold.

Authorization at the present time will be limited to use of quinine for filling physicians' prescriptions and for the manufacture of capsules. Physicians and patients who require quinine medication should purchase their supplies from local druggists or other sources of bulk quinine for prescription use as well as pills or tablets.

Because of an improved supply, totaquine may now be used for all medicinal and other purposes, WPB stated. Formerly totaquine, which represents the total alkaloids of cinchona bark, was authorized for antimalarial use only.

UNRRA COMMISSION ON QUARANTINE HOLDS MEETINGS

A series of meetings was recently held at UNRRA headquarters of its expert Commission on Quarantine for the purpose of making recommendations in regard to the control of yellow fever. One of the main problems discussed was the further delineation of endemic yellow fever areas in Africa and the Western Hemisphere. The recommendations of the Quarantine Commission will be acted on by the Standing Technical Committee on Health at a meeting in Washington early this fall. The control of yellow fever, including the delineation of endemic yellow fever areas and the laying down

of standards for the manufacture of yellow fever vaccine, is a responsibility placed on UNRRA by the International Sanitary Convention for Aerial Navigation of 1944. Dr. G. H. de Paula Souza of Brazil, chief of the Epidemic Control Section of UNRRA's Health Division, is secretary to the commission.

DENTAL AND MEDICAL LITERATURE NEEDED

The Medical and Surgical Relief Committee of America (420 Lexington Avenue, New York 17) has received several requests from organizations operating in France and Italy for dental and medical literature of any nature—magazines, pamphlets or books—written within the last five years. News of scientific progress made since 1940 has been inaccessible to European professional men, and in the interests of science, health and good will it is hoped that all those who can spare any such medical material will send it to the Medical and Surgical Relief Committee headquarters.

The following eight textbooks have been requested for the use of the Medical Nutrition Mission in Italy: .

- Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases, seventh edition (R. P. Strong).
- Manual of Clinical Mycology (Martin Conant et al.).
- Pediatric Dietetics, 1937 (Saxl).
- Brennermann's Loose Leaf Pediatrics, four volumes (Nelson).
- Physiological Basis of Medical Practice (Best and Taylor).
- Clinical Nutrition and Dietotherapy (McLester).
- Oral Diagnosis (Miller).
- Quantitative Clinical Chemistry, two volumes (Peters and Van Slyke).

AGE OF DENTAL OFFICERS

In the table entitled "Criteria for Separation" on page 1105 of THE JOURNAL of August 11 it was stated that the age of dental corps officers eligible for separation was 45 or over. This should have read 50 years or over.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Aug. 27, 1945.

Scientific Developments to Be Completed

Scientific developments under way when Japan surrendered will be completed, according to Dr. Vannevar Bush, chairman of the Office of Scientific Research and Development and one of the leaders in creation of the atomic bomb. Following a conference with President Truman, he disclosed that the Office of Scientific Research and Development will be liquidated in the course of time. The wartime agency was operating "full blast" when Japan quit, and it cannot be eliminated over night, he said. It is one of the smallest agencies. "It just doesn't make sense," Dr. Bush stated, "to conduct research for three years and then drop it in fifteen minutes." The Office of Scientific Research and Development has many contracts with universities and commercial firms and laboratories still in force. Much of the work now being done is being completed against its need for defense or peacetime use. The peak of personnel of the Office of Scientific Research and Development was a little over seven hundred workers, half of whom were volunteers.

Veterans' Mental Health Hazards Stressed by Colonel Menninger

Col. William C. Menninger, chief of the War Department Psychiatric Division, warns that if the 300,000 veterans discharged for neuropsychiatric reasons are unable to find jobs they may become "confirmed invalids." He also stated that 1,825,000 men rejected by the Army because of "personality disorders" will be thrown toward "mental ill health" if confronted with unemployment. Colonel Menninger informed the Senate Banking Committee that psychoneurosis is the basis for 43 per cent of Army medical discharges and that another 130,000 were released because of inadaptability or ineptness; 39 per cent of the 5,650,000 men rejected by the Army, or 1,825,000 men, were turned down "because they were suffering from some type of personality disorder." In his testimony on the Senate study of jobs-for-all legislation to enable the government to plan against depressions and unemployment, Colonel Menninger said that most of the Army's psychiatric casualties were "children of the depression" who grew up when there were 8,000,000 unemployed.

General Bradley Gets First Hand Medical Information

Gen. Omar Bradley, veterans' administrator, recently sent a medical staff composed of reserve officers to tour the country for first hand information on veterans' medical facilities. This was revealed during a meeting here with representatives of the American Legion, Disabled American Veterans and Veterans of Foreign Wars. General Bradley also disclosed that he is attempting to use 100 beds each in Walter Reed and the Bethesda Naval Medical hospitals to combat overcrowded conditions in Mount Alto Hospital and is moving the crowded District of Columbia regional office nearer to his office to save veterans from "shuttling back and forth" attending to their affairs. Veteran groups regard all three disclosures as indicative of good treatment from the new administrator.

Federally Financed Lanham Act Projects Cut Down

Federal Works Agency regional officials throughout the country have been instructed to review the need for continuance of aid to wartime facilities after October 31. However, \$8,000,000 in Lanham act construction, which includes the new Georgetown and George Washington hospitals, will "very likely" not be affected by liquidation of aid to war centers. Under the Lanham act, cities with populations increased by an influx of

war workers received federal assistance toward maintenance and building of child care centers and hospitals and for provision of municipal services, recreation and health programs. In Washington some forty-eight nursery schools and child care centers having an enrolment of 700 children will be affected. Major Gen. Philip B. Fleming, head of the Federal Works Administration, said that all federally financed Lanham act projects on which construction has not yet begun will be suspended immediately and allotments rescinded. Projects under construction may continue either to completion or to completion of a useful unit of the project if need for the project can still be shown to exist.

Slight Increase in Number of Women Medical Students

Despite desperate need for civilian doctors during the war, there has been only a slight increase in the number of women doctors. According to a report of the Women's Bureau of the Department of Labor there were 1,146 women students in approved medical schools in 1943 and 1,176 in 1944. The report gives these reasons: "Length of the training program for medicine as compared with other professions is of itself a deterrent to many women, since it not only increases the total cost to the student but also postpones the date she can begin to earn. . . . Since the war, tuition fees for medical schools have increased; in 1943 they were \$409, compared with \$378 in 1940."

Warning of Dangers in the Use of DDT

The similarity of DDT to flour was cited by medical authorities in warning consumers of dangers in having it stored in the household. Since the surrender of Japan the insecticide, developed during the war and restricted to army use to keep down disease in battle areas, has been more and more in the news with the prospect of its release for general civilian use. Already chemical firms are planning its distribution on a large scale. Washington authorities are also watching with interest the experiment at Rockford, Ill., where 1,100 gallons of DDT was spread over the community to control an outbreak of infantile paralysis.

Army Research on Artificial Limbs

Brig. Gen. Eugene A. Regnier, former cavalry officer, regarded as a topnotch administrator, has been appointed by Gen. Brehon Somervell to head the Army Service Forces Research and Development Division. General Somervell has ordered Regnier to make development of better artificial arms and legs his top priority job and to speed work of medical research officers, "whose efforts thus far in this field have been inadequate." General Regnier will try to translate Somervell's orders into something tangible for servicemen who have been disappointed with artificial limbs supplied by the Army.

Construction of Four Hospitals Approved by President

Veterans Administration announces that President Truman has approved construction of four hospitals: (1) an 1,800 bed neuropsychiatric hospital on a 713 acre site at Camp Reynolds, Greenville, Pa.; (2) a 300 bed general medical and surgical hospital at Seattle on a 44½ acre Beacon Hill site given by the city; (3) a 250 bed general medical and surgical hospital at Fresno, Calif., on a 20 acre site given by the city; (4) a 250 bed general medical and surgical hospital at Iron Mountain, Mich., on a 30 acre plot known as the von Platten-Fox site.

Proposed Creation of U. S. Public Welfare Department

Administration leaders have drafted plans for creation of a new department of government, the Department of Public Welfare. As outlined, it would include the Federal Security Agency, the Public Health Service, the Children's Bureau of the Labor

Department and possibly others. It would be headed by a new cabinet officer. If created, it would be the first new department established since the Department of Labor was set up thirty-two years ago.

Mothers Protest Closing of Child Care Centers

Since the announcement that withdrawal of Lanham act funds will result in closing of fourteen of twenty-two child's care centers in the District of Columbia, worried mothers in a meeting have demanded an extension of federal funds for the centers.

Penicillin Released From War Controls

The War Production Board announces that penicillin has been removed from all restrictions as to use and allocation, effective August 31.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Group Health Doctors' Plan Speeds up Enrolment

The board of directors of Group Health Cooperative in New York City, which operates a plan of insurance against doctors' bills, announced at its meeting June 27 that since Visiting Nurse Service was added to the plan's benefits on June 1 there has been the most rapid increase in enrolment in its history.

"More than 3,500 new subscribers have been secured during the month of June so far," Mr. Charles Marlies, president of Group Health, said. "In every case, employers are paying either a large share or all of the premiums for their employees. In several instances the Group Health Plan is a part of agreements with trade unions. Corporations which have taken the plan are in a wide variety of industries.

"This increasing interest on the part of employers," Mr. Marlies pointed out, "shows a growing recognition of the value of insurance against the costs of medical care as an essential element in employee welfare programs. Progressive management sees the need of average families to put medical expenses on a budgetable basis."

Eighteen Million Covered by Blue Cross Plans

More than a campaign promise or a majority vote is required to furnish adequate hospital and medical care to every one in America. C. Rufus Rorem, Ph.D., director of the American Hospital Association's hospital service plan commission, Chicago, declared in Philadelphia on June 14 during an address at a Regional Conference of fourteen Blue Cross plans.

Mr. Rorem made his statement in reference to the newly introduced Murray-Wagner-Dingell bill, now before the United States Congress, which proposes (among other phases of social security) a federal plan of compulsory health insurance, and to similar bills now before some state legislatures.

The commission, which Mr. Rorem directs, is the national coordinating agency for eighty-four nonprofit Blue Cross health service prepayment plans with a voluntary membership of 18,000,000 persons in forty-three states, seven Canadian provinces and Puerto Rico.

For more than twelve years, Mr. Rorem said, the American Hospital Association has recognized the value of the insurance principle for lightening the financial burdens of patients and stabilizing the income of hospitals. "What the federal bill proposes," he stated, as far as its health provisions relate to the employed population and members of their families, "the Blue Cross plans are achieving and have for the past ten years. The Blue Cross movement has not been crystallized into a final pattern," the director of the commission emphasized. "Executives and trustees of these nonprofit community organizations recognize that their success in reaching 18,000,000 Americans is a challenge to extend the protection to every employed person and family dependent throughout America."

Bureau of Information

SUMMARY SHEETS FROM WASHINGTON

Completed county summary sheets have been received from counties in Washington through Dr. A. J. Bowles, secretary, Washington State Medical Association.

The accompanying table gives data from selected counties in this state. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratios, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help

Washington

1. Bureau of Census, estimated population 1943.

2. Bureau of Census, population 1940.

3. Based on 1940 figures, American Telephone and Telegraph Company.

maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

FOUR STATES NOT YET REPORTED

In recent weeks, many requests have been made by veteran physicians for help with their problems of returning to civilian practice. Where information about the medical and economic factors of counties is lacking, it is impossible to give these men the help they need. Those states and counties which have not returned completed county summary sheets are urged to do so as quickly as possible so that the Bureau of Information can more fully accomplish its aims of giving adequate help to physicians returning from service with the armed forces.

County summary sheets have not yet been received from four states. Those states from which no returns have been received include Delaware, Oregon, Rhode Island and Vermont.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Officers.—Dr. Elmus K. Hanby, Attalla, has resigned as acting health officer for Etowah County, effective August 1, to devote more time to private practice (THE JOURNAL, July 21, p. 891).

Cancer Clinic.—The Alabama Division of the Field Army, American Cancer Society, recently opened its second industrial cancer clinic at Talladega. The first is at Avondale Mills, Sylacauga. The new clinic was made possible through the Bemis Brothers Bag Company, Talladega, and members of the Talladega County Medical Society are cooperating in examining the patients. Men and women are examined at the clinic.

Concentrated Attack on Venereal Disease.—Of the more than 260,000 persons in Jefferson County examined for venereal infections in a recent six week period more than 3,000 were found to have early syphilis. The total examined represents 90 per cent of the population of the county, which is the ninth in the state to launch a concentrated examination campaign authorized by the 1943 legislature when it passed a law requiring all persons in the state between the ages of 14 and 50 to have a blood examination. Those found with syphilis are to get treatment either from a physician or free through the state department of health. The U. S. Public Health Service, the state department of health and the county and city health departments of the state are cooperating in the survey, which is broadened in the attempt to uncover also venereal diseases other than syphilis. According to the *Southern Medical Journal*, reports in the medical literature suggest an estimate that one person in every ten in Alabama has syphilis.

DISTRICT OF COLUMBIA

Frederick Gillick Resigns.—Dr. Frederick G. Gillick has resigned as chief of the bureau of venereal disease in the district health department to resume work with the U. S. Public Health Service, according to the *Washington Star*. Dr. Gillick has been connected with the department since 1943.

Tuberculosis Association Creates Bureau of Information.—The District of Columbia Tuberculosis Association, through its recently developed bureau of information, offers information in relation to health and community services in the control of tuberculosis in the District of Columbia; assistance in how best to use all available diagnostic facilities, such as x-ray equipment and sputum examinations; literature on tuberculosis; diagnostic standards; x-ray interpretations; booklets and pamphlets on family health education for office distribution to patients, and health education for patients and families on referral. Rebecca Sweeney, R.N., is secretary of the bureau of information, 1601 18th Street N.W.

ILLINOIS

Changes in Health Officers.—Dr. Samuel N. Mallison has resigned as superintendent of health of Decatur, effective August 1, to join the state department of health as district No. 6 health officer with headquarters in Champaign. He will be in charge of the district including Livingston, Kankakee, Ford, Iroquois and Vermilion counties.

Committee Named for Hospital Study.—Dr. Henrietta M. Herbolzheimer, acting chief of the division of maternal and child hygiene, state department of health, Springfield, has been named secretary of an executive committee to conduct a survey of Illinois hospital facilities. Newspapers report that the group will operate under authority of an advisory council appointed by Governor Green to determine hospital needs throughout the state.

Chicago

Personal.—Alden B. Mills, managing editor since 1933 of the *Modern Hospital*, has resigned to become superintendent of the Collis P. and Howard Huntington Memorial Hospital, Pasadena, Calif.; he will take up his new work October 15.

School for Medical Librarians.—The Wesley Memorial Hospital announces the opening of a School for Medical Records Librarians, the first class to begin September 25 and the second February 12. The new school, conducted as a subdivision of the program in hospital administration at Northwestern University, makes it possible to grant university credit totaling twenty-four semester hours to students who successfully complete the courses. Edna K. Huffman, R.R.L., chief medical records librarian, Wesley Memorial Hospital, has been named director of the school, which is being sponsored by the hospital administration division, School of Commerce, Northwestern University. Additional information may be obtained from Mrs. Huffman at Wesley Memorial Hospital, 250 East Superior Street, Chicago 11.

MASSACHUSETTS

New Director of Mental Hygiene.—Dr. William C. Inman, Danvers, has been appointed director of the division of mental hygiene and research of the Massachusetts State Department of Mental Health. Dr. Inman succeeds Dr. Edgar C. Yerbury, who resigned to become superintendent of the Connecticut State Hospital, Middletown, Conn. (THE JOURNAL, July 22, 1944, p. 858). Dr. Inman graduated at Tufts College Medical School in 1924. For the past few years he has been assistant superintendent of the Danvers State Hospital, according to the *Bulletin* of the Massachusetts Society for Mental Hygiene.

MICHIGAN

Fellowships in Psychiatry.—Dr. Albert C. Furstenberg, dean, University of Michigan Medical School, Ann Arbor, announces that there are ten one year fellowships in psychiatry now available at the university. These fellowships, which offer an annual stipend of \$2,000 and which are under the sponsorship of the Office of Veteran's Affairs of the State of Michigan, include training at the Neuropsychiatric Institute of the university. Candidates must be graduates of an approved medical school and must complete a rotating internship before beginning their fellowship. Applications should be made to Dr. Raymond W. Waggoner, professor of psychiatry, University Hospital, Ann Arbor.

Health Officers' Committee Named to Advise State Commissioner.—A five member committee from the Michigan Health Officers Association has been appointed to serve in an advisory capacity to the state commissioner of health. Members of the committee, who will meet once a month with Dr. William DeKleine, state health commissioner, to discuss problems and exchange ideas, are Drs. Hugh B. Robins, Marshall, Calhoun County; Bruce H. Douglas, Detroit; Richard Sears, Marquette; Leslie V. Burkett, Flint, Genesee County, and Albert E. Heustis Jr., Coldwater, Branch County. Dr. Clarence D. Barrett, Mason, health officer of Ingham County and president of the state health officers' association, is an ex officio member of the committee.

NEBRASKA

New Health Director of Lincoln.—Dr. Leroy L. Fatheree, since 1939 health officer of Little Rock, Ark., has been named director of the board of health of Lincoln, effective July 14. Dr. Fatheree graduated at the University of Tennessee College of Medicine, Memphis, in 1936.

Special Society Election.—Dr. John F. Gardiner, assistant professor of medicine, Creighton University School of Medicine, Omaha, was elected president of the Nebraska Tuberculosis Association at its annual meeting June 12. Other officers include Dr. Charles W. Way, Wahoo, and O. W. Ortlund, Omaha, vice presidents, and Clark S. Haas and Fred W. Conrey, Omaha, reelected secretary and treasurer, respectively.

Institutes on Tuberculosis.—Two one day institutes on tuberculosis were held at the Nebraska Hospital for the Tuberculous, Kearney and Omaha, August 6 and 8 respectively, according to *Better Health*, the bulletin of the state department of health. Among the speakers were:

Dr. Charles W. Rudolph, medical director, Hospital for the Tuberculous, Kearney.

Dr. Max Fleishman, medical director, tuberculosis service, Douglas County Hospital, Omaha.

Dr. Theodore F. Hilbish, tuberculosis consultant, U. S. Public Health Service, district 7, Kansas City, Mo.

Dr. Claude A. Selby, director of health, Nebraska State Department of Health, Lincoln.

Dr. Llewellyn E. Kling, Bellevue, director, state division of tuberculosis control.

Miss Margaret Taylor, R.N., public health nurse consultant, division of tuberculosis, U. S. Public Health Service, Washington, D. C.

Miss Lily C. Hagerman, R.N., public health nurse consultant, U. S. Public Health Service, district 7, Kansas City.

NEVADA

Dr. Caples Resigns.—Dr. Byron H. Caples, Reno, has resigned as director of the division of venereal disease control of the Nevada State Department of Health, effective June 30. Dr. Caples had held the position since 1937.

NEW YORK

Fund Named for Physician.—The will of Mrs. Charles E. Townsend bequeathed her residuary estate to St. Luke's Hospital, Newburgh, with the stipulation that it be known as the Dr. Charles E. Townsend Fund. It is estimated that the bequest will amount to approximately \$500,000. Dr. Townsend was president of the board of managers, consulting surgeon and at one time chief surgeon and chief of the hospital staff at St. Luke's. He died March 16, 1942.

Physician Membership Increased on Medical Care Commission.—On June 30 Governor Dewey appointed Drs. Harold F. R. Brown, Buffalo, and Andrew A. Eggston, Mount Vernon, as members of the New York State Temporary Commission on Medical Care, increasing the physician membership on the commission from four to six. The commission was created by the 1944 state legislature to make studies, surveys and investigations for medical care and to prepare recommendations for the Legislature. The original membership of the commission included four doctors of medicine, but action of the recent legislature increased the membership to six.

Cancer Teaching Day.—On September 18 a cancer teaching day will be held at the Middletown State Homeopathic Hospital, Middletown, under the auspices of the Medical Society of the County of Orange, Tumor Clinic Association of the State of New York, the state medical society and the division of cancer control of the state department of health. Speakers will include:

Dr. Earl D. Osborne, Buffalo, Cancer of the Skin and Allied Tumors.
Dr. Arthur J. Wallingford, Albany, Cancer of the Uterus and Vagina.
Dr. Hayes Martin, New York, Diagnosis and Curability of Intraoral Cancer.
Dr. Cushman D. Haagensen, New York, Cancer of the Breast.
Dr. George E. Binkley, New York, Cancer of the Colon and Rectum.

Mental Clinics for the Public.—The Westchester County Health Department was authorized August 6 by the board of supervisors to operate clinics for the mental care of persons who cannot afford private psychiatrists and psychologists. Credit is ascribed to the Westchester Mental Hygiene Association for launching the campaign to hold these clinics, which for the time will be known as "health clinics" and serve all residents. The supervisors appropriated \$15,000 for starting the first clinic, more funds to be made available as needed. It is expected that five or six clinics will be operating in various parts of the county by next year, costing annually an estimated \$75,000. For the present a psychiatrist, a psychologist and two social workers will start work in White Plains and sit occasionally in Mount Vernon. The communities of Westchester that are not in the county health district will be served on request.

Rehabilitation of the Blind.—A newly created rehabilitation division in the New York State Department of Social Welfare will administer a program to assist the blind set up under the federal vocational rehabilitation act. The program provides for rehabilitation of all blind persons over 14 years of age who need physical restoration, vocational training or job placement to fit them for self-supporting employment. The program will include medical, surgical, neurologic and related services; vocational training, including academic, technical and other courses; job placement and supervision of employment until the blind person becomes self sufficient, and studies and research. A general advisory committee will be appointed by Robert T. Lansdale, state social welfare commissioner, to advise the new division on general policies and standards and to assist in interpreting the program to the public. It will consist of representatives of management, labor, the medical profession, and public and professional and civic organizations identified with vocational rehabilitation of the handicapped. An advisory medical committee will also be set up, representing all specialized branches of medicine, public health nursing, hospital administration and social work. Among its members will be an ophthalmologist from the medical and advisory committee of the state commission for the blind, a member from the medical division of the social welfare department and a member of the general advisory committee, who will be the chairman. The medical committee will work cooperatively with the general advisory committee.

New York City

University News.—Dr. Louis Hausman has been appointed clinical professor of neuropsychiatry at the New York University College of Medicine, effective September 1, and Dr. Charles W. Depping assistant clinical professor of otorhinolaryngology. Dr. Renato Gazmuri, instructor of internal medicine, University of Chile, Santiago, has joined the department of physiology as a Rockefeller fellow. Ivan C. Hall, Ph.D., has resigned as professor of bacteriology and director of the department of bacteriology of the college.

Hospitals Merge.—Beekman Hospital and the Downtown Hospital are consolidating and will form a new institution to be known as the Beekman-Downtown Hospital, to be centrally located in the financial section of the city. It is planned to hold a public campaign for funds to erect a new building to hold about 200 beds and to be conducted later this year. The Beekman Hospital has a fund of \$500,000 in escrow which will be used toward the cost of the new building. Beekman Hospital was founded in 1906 under the name of St. Gregory's Hospital. Downtown Hospital was established in 1916 under the name of Broad Street Hospital.

Mother's Aide Program.—The New York City Department of Welfare has inaugurated a new service to be known as the "Mother's Aide," which is designed to prevent unnecessary commitment of children to institutions when mothers are temporarily ill, either in a home or in a hospital, by providing care for them in their own homes. The city's budget provides for forty-five of these aides at annual salaries of \$1,440 as for an administrative staff of five persons consisting of supervisor and four investigators. It is expected that the program will not only alleviate the critical shortage of facilities for short term placement of children but avoid the psychological shock to the child of institutionalization.

Warning on Typhoid.—The New York City Department of Health has issued an appeal to city residents who may have stopped at the Seacliff Hotel in Bradley Beach, N. J., recently to report to the department so that proper precaution may be taken to prevent a spread of typhoid which originated at the New Jersey hotel. Investigation by the New York City Health Department has revealed that 4 New York City vacationists developed typhoid and 14 additional New Yorkers are known to have been in the hotel on or after July 13, when exposure is presumed to have taken place. The New Jersey State Health Department, which traced the outbreak to kitchen employee at the Bradley Beach resort, has already reported that there are 14 cases of typhoid among former hotel guests in addition to 4 cases discovered so far in New York City. The majority of patients became ill during the period July 23 to August 3. The city appeal was issued because the hotel register is said to be incomplete.

OHIO

New Dean of Pharmacy.—Arthur Paul Wyss, Ph.D., professor and head of the department of pharmacy at the University of Buffalo, Buffalo, N. Y., has been appointed dean of the School of Pharmacy at Western Reserve University, Cleveland. He succeeds Franklin J. Bacon, Ph.D., professor of botany and pharmacognosy, who accepted the temporary appointment last year when Edward D. Davy, B.S., resigned to become head of the division of pharmacy at the Winthrop Chemical Company, Rensselaer, N. Y.

Veterans Collateral Pool Fund.—The Columbus Academy of Medicine has established a Veterans' Collateral Pool Fund of \$50,000 for "assisting, in a material yet uncompromising way, the returning veteran members of the Columbus Academy of Medicine who may need financial assistance in establishing or reestablishing themselves in the practice of medicine." The state medical journal points out that the Columbus plan is unique. Physicians were requested to purchase one or more 1.5 per cent U. S. Treasury Coupon Bonds, due in 1950, in the amount of \$500 each and to agree that the bond be placed in a pool to be held for a period of five years if necessary. The pool is to be used in providing collateral for loans to be made by a Columbus bank, the pool to be under the supervision of the veterans' committee of the academy of medicine. The veterans' committee and the officials of the bank are to determine the necessity, reasonableness and amounts of all loans applied for.

Proposed State Health Center.—A proposal is before Governor Frank J. Lausche of Ohio and members of the legislature for the erection of a state health center at Ohio State University, Columbus, Science reports. An appropriation of five million dollars is requested to cover the cost of the center as the result of two years of planning and study by

members of the medical and dental faculties and by representatives of these professions. The proposed center has been approved by official representatives of the medical colleges of Western Reserve University, Cleveland, and the University of Cincinnati. It has also been approved by the Inter-University Council, which includes representatives of the six state universities, Bowling Green State College, Kent State University, Miami University, Oxford, Ohio University, Athens, and Ohio State and Wilberforce University. Joining also in active support of the project are medical, dental and nursing alumni of the Ohio State University under the chairmanship of Dr. Russel G. Means, Columbus.

TEXAS

Osteopaths Defeated in Injunction Proceedings Over EMIC Program.—The Third Court of Civil Appeals, Austin, recently denied to osteopaths an injunction to restrain the state board of health from carrying out the EMIC program until the program had been modified to permit osteopathic participation. The plan in operation in Texas at the time limited participation, as far as medical services other than obstetrics were concerned, to graduates of medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association. As to pediatric services to newborn infants referred by obstetricians, the plan limited participation to specialists certified by the American Board of Pediatrics or physicians who have completed at least one year of graduate training in a pediatric residency approved by the Council on Medical Education and Hospitals. Such restrictions, the osteopaths claimed, wrongfully deny to them the right of participation. The court pointed out, however, that under the federal law authorizing the program a state board of health acts not as a state agency but as an agency of the federal government through which the funds for the program are to be expended, that the plan in operation in Texas was one outlined by the Children's Bureau and approved by it and that state courts have no jurisdiction over the United States or its agencies charged with the administration of the provisions of the appropriation act authorizing the expenditure of funds for the program. The court, therefore, denied the petition for the injunction.

ALASKA

Health Activities.—A survey of health conditions on Seward Peninsula, as well as northern parts of Alaska, is to be carried out for westward and interior Alaska. The disease control program will consist of case finding, diagnosis and rapid treatment, with administration of immunization, chest roentgenograms, education in nutrition and a venereal disease program. It is said that the health of the Eskimos demands particular attention. They will be included in this health survey; *Northwest Medicine* reports that an investigation was recently instituted in Alaska by leading Ketchikan physicians, together with the Territorial Health Department and local health workers, to find the cause of outbreaks of intestinal illness existing for several years in Ketchikan and that vicinity. Information will be sought from persons who are known to have suffered intestinal illness of unknown origin during past months. An intensive survey was contemplated to secure this information.

GENERAL

Examination in Otolaryngology Canceled.—The Chicago meeting of the American Board of Otolaryngology, scheduled to be held in October, has been canceled. The next examination will be conducted in the spring, the exact time and place to be announced later. Dr. Dean M. Lierle, University Hospital, Iowa City, is the secretary-treasurer of the board.

Markle Foundation Publishes Report.—The John and Mary R. Markle Foundation appropriated more than \$500,000 in 1944 for all purposes, according to its annual report just made available. Appropriations included \$323,564 for research in the medical and physical sciences, \$79,645 for old age assistance and relief to individuals, \$38,500 for special contributions and \$78,375 for administrative and general expenses.

James Fieser Joins National Safety Council.—James L. Fieser has been appointed to the staff of the National Safety Council to develop a nationwide public service program in home, traffic, farm, school and public safety. Mr. Fieser, who for more than twenty-seven years has been with the American Red Cross, has resigned as vice chairman at large of the Red Cross and was to assume his new activities September 1 with headquarters in New York.

Wallace Graham Named Personal Physician to President Truman.—Lieut. Col. Wallace H. Graham, M. C., formerly of Kansas City, Mo., is to be personal physician to President Truman, according to the Associated Press, August 13. Colonel Graham is 34 years of age and the son of Dr. and Mrs. James W. Graham, Kansas City. He graduated at Creighton University School of Medicine, Omaha, in 1936 and subsequently studied at Harvard University and in Vienna.

Proposed Measures to Prevent Rise in Drug Addiction.—New international measures to prevent a postwar rise in drug addiction were recommended August 13 by the Bureau of Narcotics, U. S. Treasury, according to the *New York Times*. In a report for 1944 on the traffic in opium and other dangerous drugs, the bureau said that important stocks of drugs were being held in certain countries by traffickers who awaited a chance to ship them to the United States for distribution. Iran, India and Mexico were the chief sources of opium smuggled into the United States last year, it was stated. There was a sharp rise in opium seizures, especially at Atlantic ports and along the Mexican border. The largest single seizure made by U. S. customs officers in six years, despite restrictions on shipping, was 63 pounds of opium sent from India and taken from Baltimore.

Special Society Elections.—Dr. Custis Lee Hall, Washington, D. C., was chosen president-elect of the United States chapter of the International College of Surgeons at a recent meeting in New York and Dr. Herbert Acuff, Knoxville, Tenn., was installed as president. Other officers include Drs. John Royal Moore, Philadelphia, senior vice president; Drury Hinton, Drexel Hill, Pa., treasurer, and Louis J. Garipey, Detroit. Dr. Max Thorek, 850 West Irving Park Road, Chicago 13, is the international general secretary of the International College of Surgeons.—At the annual meeting of the board of trustees of the American Registry of X-Ray Technicians in Chicago, June 17, Dr. Darmon A. Rhinehart, Little Rock, Ark., was elected president, Dr. Sidney J. Hawley, Danville, Pa., vice president and Dr. John M. Keichline, Huntington, Pa., secretary-treasurer. Mr. Alfred B. Greene, Oak Terrace, Minn., was reappointed executive secretary.

Plan to Accredit Schools of Public Health.—The Commonwealth Fund has made available funds to the American Public Health Association to "create a properly constituted accrediting body to carry forward progressively a list of universities qualified with regard to program, personnel and facilities, to offer adequate courses leading to degrees of master of public health, doctor of public health and the diploma in public health." Charles-Edward A. Winslow, Dr. P.H., New Haven, has been named counselor to be responsible for the investigative work. He will be aided by persons experienced in the administration of health departments, chosen from different localities for different schools. The present plan will be to examine schools for accreditation at their own request. First attention will be given to schools in the United States now offering the M.P.H. degree and in Canada offering a Diploma. Accreditation of field training stations and of courses for various public health specialties will not be attempted immediately, according to the *American Journal of Public Health*.

New Officers of Tuberculosis Groups.—Dr. Victor F. Cullen, State Sanatorium, Md., was recently chosen president-elect of the National Tuberculosis Association and Mr. Will Ross, Milwaukee, was installed as president. Other officers include Dr. Henry Stuart K. Willis, Northville, Mich., and Dr. Philip H. Pierson, San Francisco, vice presidents; Dr. Charles J. Hatfield, Philadelphia, secretary, and Livingston Platt, New York, treasurer. Dr. John Alexander, Ann Arbor, Mich., is the new president-elect of the American Trudeau Society, medical section of the National Tuberculosis Association, and Dr. Ezra R. Bridge, Rochester, N. Y., president. Drs. R. McLeod Riggins, New York, and Hugh B. Campbell, Norwich, Conn., are vice president and secretary-treasurer, respectively. Edward K. Funkhouser, Washington, D. C., executive secretary of the District of Columbia Tuberculosis Association, is the new president of the National Conference of Tuberculosis Secretaries. Other officers include Glenn V. Armstrong, executive secretary, Los Angeles County Tuberculosis and Health Association, vice president; Mrs. May M. Pynchon, Jacksonville, Fla., executive secretary, Florida Tuberculosis and Health Association, secretary, and Donald E. Pratt, executive secretary, Missouri Tuberculosis Association, treasurer.

Council of New England Medical Societies.—On July 18 the Council of New England State Medical Societies was organized at a meeting in Providence, R. I. All the New England states were represented by delegates with the exception of Maine, these delegates being unable to attend because of transportation difficulties. The objective of the new group is to bring about a closer cooperation between the state medical societies in New England in the development and maintenance of the highest standards in the conduct and administration of medical care, in the development of plans to improve the health of all the people in the New England states. It proposes to concern itself with the problems of the composing members, avowing the principle that it shall not constrain its members to relinquish any existing affiliation, nor shall it seek to supersede the control now exercised by the governing bodies of each respective state medical society, or by the House of Delegates of the American Medical Association. The council decided to hold an annual meeting on the third Wednesday of April. Temporary officers chosen include Drs. James R. Miller, Hartford, Conn., chairman of the council of the Connecticut State Medical Society, president; John F. Kenney, Pawtucket, R. I., president of the Rhode Island Medical Society, vice president, and Mr. John E. Farrell, executive secretary of the Rhode Island Medical Society, secretary-treasurer. The next meeting of the council will be held October 14.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended August 18 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Division and State	Poliomyelitis		Division and State	Poliomyelitis	
	Week Ended 8/18, 1945	Week Ended 8/19, 1944		Week Ended 8/18, 1945	Week Ended 8/19, 1944

LATIN AMERICA

Health Activities in Latin America.—*Inter-American Typhus Conference in Mexico.*—The public health and welfare department of Mexico is calling an Inter-American Typhus Conference to be held in Mexico City from October 7 to 13 under the sponsorship of the Institute of Inter-American Affairs and the Pan American Sanitary Bureau, to bring together leading workers in the typhus field in the American republics to discuss the latest developments, both in the field of research and in the practical control of the disease. As epidemic typhus is a serious problem in many of the American republics and as leaders of the typhus control program in the United States armed forces have experienced success in the control of this disease, it is believed that the calling of such a conference is opportune. Invitations to leading scientists are being issued, but other persons who have an interest in this subject will be welcome to attend the meeting. Correspondence should be directed to the Secretaría de Salubridad y Asistencia, Mexico, D. F.

Personal.—Col. Harold B. Gotaas, Sc.D., director of the division of health and sanitation of the Institute of Inter-American Affairs, has been decorated by the Chilean government with the Order of Merit. Before joining the army in 1942 Colonel Gotaas was professor of sanitary engineering in

the University of North Carolina School of Public Health. —Dr. Joaquin J. Vallarino, chief of the x-ray section of the Herrick Clinic in Panama, is the new Panamanian ambassador to the United States.—Dr. Jean F. Rogier, formerly medical officer with the Field Party in Brazil, left Washington, D. C., June 28 to become chief of the Field Party in Paraguay.

New Construction.—Work was started in July on a new dispensary in La Boca, Canal Zone, to provide more adequate health facilities for the silver workers in the area. Under present arrangements La Boca residents receive dispensary service in Balboa.

FOREIGN

"Pool" of Physicians Created.—A pool of young physicians has been set up by the labor government in New Zealand which, according to the *New York Times*, ties physicians to the health department for from three to five years after graduation and binds them to serve in the posts and locations chosen for them. The *Times* states that the ministry of health has achieved this objective by a simple variation in the terms of the scholarships granted to the national medical school at Dunedin. First plans for the scholarships, which are granted by the government, were that they should allow brains to be sufficient qualification to study medicine and abolish the barrier represented by the need of funds to begin seven years of study. Arthur Nordmeyer, health minister, has announced, it was said, that the academic merit alone is to be the test of whether scholarships are granted and the means test is abolished. There was considerable argument between the health department and the national medical association over the terms of the scholarships when these were first drafted. The medical men were dismayed at the way in which the government had tied down the students for the years following their graduation. On the arguments of the doctors the terms were said to have been varied. But now the minister of health has announced that if a medical student is graduated on a scholarship he must carry out his pledge to serve from three to five years where the government sends him or else repay the amount of his scholarship, plus interest, and plus a penalty to be determined by the minister. The amount of this fine apparently could be varied. The change had been made, the minister frankly admitted, because "some students had openly declared their intention of terminating their contract by repayment of the scholarship money. Thus every one of the sixty-seven students who have already accepted scholarship aid and every one who does so in the future becomes drafted to three to five years' state service unless able to pay a fine that is intended to be so large as to make it hard for him to escape. The government has made this move because it needs interns for public hospitals now staggering under the load that free medical care has laid on them, but chiefly because there is what Mr. Nordmeyer calls "great scope" in back country areas, where medical services are held inadequate. In some regions, particularly mining districts where physicians have been subjected to threats if they did not grant medical certificates, it has been hard to find doctors to serve now that free consultation has stepped up city business. The health department will not require that doctors stay in these regions for long periods, Mr. Nordmeyer says, and will provide houses and automobiles. Pay for these young draftees is not to be high. It will approximate \$4,200 a year at prewar rates of exchange, no more than dock laborers have been receiving in wartime, and it will stop there unless the doctor obtains some further qualification or wins recognition as a specialist. But the winning of these qualifications is one of the strongest points of criticism of the new government plan. Strong criticism of the new move by the health minister came from the national medical association. "As originally understood, the object of the scholarships was that talent should not be impeded by lack of means," an official statement said. "It now appears that universal availability of the scholarships and the conditions attaching to them will create a pool of young doctors tied to the government and subject to direction to whatever work the government may determine. Would any trade union countenance such conditions? Evidently a large number of scholarships is contemplated, and the capacity of the medical school is limited. Will there be room for students who prefer to pay their own way, or will these have to go elsewhere? Will they be allowed to do so?" The National Medical Council also found dangers in a new government plan to permit graduate doctors to begin private practice without first spending a year in hospital work.

The Socialist Government and the Medical Profession

It was pointed out previously (*THE JOURNAL*, Nov. 4, 1944, p. 651) that the proposed national health service, which has produced the greatest crisis ever faced by the medical profession, was only one of the manifestations of the socialistic trend of British politics. The profession has been so occupied with discussion of details that it does not seem to have given this consideration due weight. It has accepted socialistic legislation as inevitable, but its representatives in negotiation with the minister of health of the late government have endeavored to secure terms acceptable to the profession. That government was a coalition of all the political parties formed for the purpose of prosecuting the war. But in spite of a predominant conservative ingredient the coalition government agreed to schemes of socialistic legislation. The chief of these was the plan for a national health service, which has been described in previous letters. "We are all socialists in these days," said a great conservative statesman many years ago, and, as wary politicians, the conservatives have seen the need to accept some socialism in order to avoid the greater evil of the return to office of the socialistic party. But this policy has not now availed them. Notwithstanding the prestige of the greatest national leader ever produced by this country, to whom an unpayable debt is owed for his unique services in her hour of greatest peril, the conservative party has sustained a crushing defeat. An attempt to explain the causes of this defeat would take one outside the province of these letters. But it may be said that the socialistic trend mentioned was pent up during the need for union of all parties in the face of the German peril, and that now the flood is let loose. Also the country decided that if it was to have socialism this would come more effectually from professed socialists than from those who were only lukewarm.

The bearing of all this on the proposed national health service will be obvious. Before the election the representatives of the profession had long negotiations with Mr. Willink, minister of health, who is a conservative and a lawyer. The negotiations have not been published, but there are indications that Mr. Willink would have tried to meet the objections of the profession and make the national service as acceptable to the profession as possible. The socialist press charged him with "surrendering to the doctors," though he seems to have only endeavored to come to an agreement while preserving essentials. Now we have a socialist government in power, and the minister of health, Mr. Bevan, is a stalwart socialist. Hence the *British Medical Journal* says that it would have been an advantage if the bill for a national health service could have been presented to Parliament by the late coalition government, in which the political forces were more or less evenly balanced. Now that the Labor party is in power the results of prolonged and difficult negotiations may be found "in the discard." In a pamphlet on a "National Service for Health" this party has declared that "only a system of whole time salaried and pensionable doctoring will meet the requirements." Now this proposal would convert the medical profession into government officials, which has been declared by the representatives of the profession to be the most objectionable feature of the scheme for a national health service.

Hospital Reform

The government project for a complete national health service has led the Ministry of Health to make a hospital survey and ascertain what facilities exist, to assess their adequacy and suggest how they can be coordinated and expanded to provide

a complete and efficient service. For this purpose England and Wales have been divided into ten areas, of which London and the surrounding area are one. A report on this area by Drs. A. H. M. Gray and Andrew Topping has been published. The inhabitants number 14 million. There are some 380 governing bodies of voluntary hospitals, 25 major hospital owning local authorities, 20 minor authorities with maternity homes and 130 isolation and smallpox hospitals also provided by local authorities. As a result, admission to municipal hospitals is often hampered by administrative boundaries, while the independence of the voluntary hospitals has caused dispersal and competition instead of concentration into efficient units. In 1938 the voluntary hospitals admitted 473,000 and the municipal hospitals 477,000. But the voluntary hospitals dealt with eight times as many outpatients as the municipal.

The report is critical of the large amount of surgery done in the small hospitals by general practitioners, which is a reflection of the poor distribution of consultants in the area. Further, the care of the chronic sick is far from satisfactory. In the area as a whole there is a gross deficiency of beds.

Gray and Topping condemn the general practitioner hospital as a surgical specialist center. Each such hospital, they said, should be attached to a district hospital staffed with specialists. The function of the local general practitioner hospital should be for medical cases not requiring elaborate investigation but not suitable for nursing at home, for minor operations (excluding removal of tonsils and adenoids), for normal maternity cases, for the few urgent emergencies and accidents which cannot be taken to a district hospital and for convalescents. Specialists should visit the local hospitals regularly and hold outpatient clinics there. The main district hospital should not exceed 1,000 beds or fall below 400. A third type of "the special center" is proposed to serve areas much wider than those of district hospitals. These would include special hospitals, such as fever, chest or orthopedic. The most urgent single improvement would be in the staffing of hospitals. To make the best use of the specialists available, decentralization from London is urged. Payment of the specialists should be adequate for breaking their ties with London.

Reform of Medical Education and Organization

Robert Debré presented to the Comité des médecins français an interesting report on the professional organization of medicine and medical education. Debré believes that it should be possible to adopt the most audacious modern innovations along with the traditions which contain excellent elements and to restore to medicine the noble character of a liberal profession, while at the same time creating a solid sanitary framework under the surveillance of the state or other collective bodies. Equality must be realized among the French as regards health matters. It is necessary to assure to all patients the privilege of a professional secret, within reasonable limits, and free choice of the physician, the moral and therapeutic value of which is considerable. The reforms are to be based on the following principles:

1. The practitioner must retain the privilege of serving. This was well expressed by Duhamel, who said "The practice of medicine rests on a moral ideology, which generally is referred to as conscience; conscience is individual. . . . To give up individualism under conditions prevailing in the world today would be an act of resignation for a clairvoyant spirit, or, more exactly, a suicide. Since medicine has for its mission the assisting of man in the essential acts of his life, such as birth, suffering and death, medicine must remain one of the redoubts of individualism in danger."

2. Each French family should have an independent practicing physician.

3. The hospital, the medical personnel of which will be fixed and on full time, must absorb the private organizations and clinics and put at the disposal of the whole population and under the supervision of the faculty of medicine the center for diagnosis and treatment.

4. The teaching body must devote itself completely to its task and must lead essentially a hospital and university life.

5. To the faculties of medicine will be entrusted the technical direction of hospital services, the regional supervision of hygiene, the contact with practitioners, the courses of postgraduate instruction, the direction of the profession toward a close participation in national propaganda for sanitation and the organization of preventive medicine.

However, in this liberty and in this initiative given to the medical profession, the state will have its part. The state will conduct the financing and will set in motion and will maintain the administrative features of all these organizations. The state will carry through the work of prevention, the starting point of which will be the family physician, because the family is the initial unit.

Experimentation on Man

Christian Charpy presented to the Académie de médecine authentic documents which fell into the hands of the French police in the course of the invasion of Germany, and which establish irrefutable proof of experimentation on prisoners, performed not by the executioners but by German scientists. Histologic preparations of human testes and epididymides were found in the laboratory of Professor Hirth of Strasbourg. There were 54 preparations from 7 persons. Charpy produced reproductions of these preparations. They were not those of normal tissue. Some showed considerable edema with desquamation of the vascular walls, occasionally massive, at other times limited to the seminal epithelium, agglutination of seminal elements and homogenization of localized groups of interstitial cells. In other preparations edema appeared to be in the process of resorption, the congestion was less severe and a number of seminiferous tubules were reduced to a state of cellular uniformity; in others the spermatogenesis was arrested, while still others were represented by a cicatrix. The lesions were not generalized or homogeneous as, for example, after irradiation, in alimentary disturbances or in general intoxication. They were limited and appeared as spindles throughout the gland or through one lobe, the rest of the gland being little or not at all involved. Such lesions are produced when intraparenchymatous injections with toxic or irritating substances are made. The injecting needle reaches some tubes or certain lobes more directly, to the exclusion of others. "One cannot imagine," says Charpy, "other means capable of producing these lesions than the injection on the living." It is incontestable that these specimens came from experiments made on living man and sometime before death: eight or ten days or even longer. Even supposing that these injections were made under anesthesia, it is certain that the secondary reaction, the congestion and the edema caused pain. The aim of these experiments was probably an attempt to perfect an injection capable of sterilizing a man. The fact that the fixation was good indicates to the histologist that the patients were sacrificed immediately before the removal of the specimen. The volume of 2 of the specimens indicated that they were from testes of children aged 13 and 15 years. The Académie decided to break off all scientific relations with the German scientists until such time when they shall have rigorously cleansed their scientific organizations. Other proofs not less valid than those of Professor Charpy demonstrated that man was regarded by the Germans as a guinea pig.

Dr. Henri Chrétien, who was held for two years in a torture camp, furnished information collected first hand regarding methods of scientific extermination. He saw arrive at his camp, in the Vosges, two groups of 40 Gypsies each. The following day, a professor from Strasbourg in SS uniform, accompanied by an orderly, inoculated typhus by scarification into one of the groups. Dr. Paulson, detained Norwegian physician, was charged to look after the "experimental animals." All developed typhus. Another group of Gypsies were subjected to tests with toxic gases; others were assigned for experiments on freezing.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, July 30, 1945.

Special Medical Courses

In connection with the regular work of the University of Rio de Janeiro, an intensive postgraduate course in obstetrics and gynecology is being given during the current month at the Hospital Pro-Matre under the direction of Dr. J. M. Moniz de Aragão, associate professor at the university. Besides Dr. Aragão, Drs. Octavio de Souza, J. Berla de Niemeyer, Goulart de Andrade, Humberto F. Faria and C. Correa da Costa are in charge of the lectures and practical demonstrations included in the course. Cancer of the uterus, anomalous nidation, feminine sterility, sudden death during labor, brucellosis during pregnancy, the x-rays in obstetrics and fetal erythroblastosis are among the special topics included in the course.

A postgraduate course in plastic surgery is now being given at the University of São Paulo under the direction of Dr. J. Rebelo Neto, head of the department of plastic surgery at the Santa Casa Hospital of that city. Dr. Duarte Cardoso and Dr. Victor Spina are also in charge of the course, which includes lectures, practical demonstrations and operations.

A special course in medical psychology and cerebral physiology will be given at the Policlinica de São Paulo. Dr. Francisco Tancredi and Dr. Annibal Silveira are in charge of the lectures and practical demonstrations of the course.

The Hospitals of the City of Rio de Janeiro

The city of Rio de Janeiro (Federal District) has at present ninety-five hospitals, adding up a total of 18,211 beds, with an average of 191.7 beds per hospital. For the population of 1,950,000 these figures correspond to 20,526 persons for each hospital and 107 persons for each bed. The largest institutions are the Misericórdia General Hospital (991 beds), the Portuguese General Hospital (585 beds), the Juliano Moreira Suburban Psychopathic Colony (2,800 beds), the Army Central Hospital (868 beds), the Carupaity Suburban Leprosarium (594 beds) and the St. Sebastião Tuberculosis Hospital (500 beds). These hospitals are divided into three main groups: the private institutions, of which there are sixty-seven with 7,101 beds (or 105.9 per hospital), the federal institutions, numbering eleven with 7,530 beds (or 684.5 per hospital) and the municipal institutions, seventeen with 3,580 beds (or 210.6 per hospital).

According to the specialties, these institutions are divided into thirty-eight general hospitals with 8,112 beds, nine hospitals for surgery only with 423 beds, five children's hospitals with 414 beds, thirteen maternities with 532 beds, seventeen psychopathic hospitals with 6,519 beds, ten hospitals for the tuberculous with 1,403 beds, one for the isolation of acute transmissible diseases with 90 beds, and two for the leprosy with 718 beds. Among the general hospitals three are military, the Army Central Hospital with 868 beds, a navy hospital in an island of the bay with 434 beds, and the small but good Central Hospital of the Air Ministry with 181 beds, where several American service men have been treated. There are at present annually

in Rio de Janeiro about 36,000 births, 6,200 deaths from tuberculosis, 6,000 deaths of infants and 12,000 known cases of acute transmissible diseases (and about 30 per cent more of unknown cases). The largest number of beds for mental cases are in federal hospitals, because these hospitals are included in the Division of Mental Hygiene of the National Department of Health. An ambitious plan of extension and improvement in the hospitals of Rio de Janeiro is now being carried out by the city administration. A modern municipal general hospital with about 600 beds is almost completed. This hospital will be known as the Pedro Ernesto Hospital, the name of a popular physician who was mayor of Rio de Janeiro from 1931 to 1935.

Extension of the Area of Visceral Leishmaniasis in South America

Dr. Madureira Pará, pathologist of the Laboratory of the Rockefeller Foundation in Rio de Janeiro, has confirmed a diagnosis of visceral leishmaniasis after the examination of the material sent from a case in the republic of Colombia by Dr. Augusto G. Gast of the Service of Viscerotomy of the Division of Special Studies of the Ministry of Labor, Hygiene and Social Welfare. During his routine of viscerotomy in connection with the yellow fever work, Dr. Gast found a sample of liver taken from the dead body of a 3 year girl from San Vicente de Chucuri, Santander, Colombia, with abundant forms of Leishmania. Since this would be the first case of infantile kala-azar registered in the country, the material was sent for a more careful examination to the Rio de Janeiro laboratory. The case occurred in a rural mountainous district at the altitude of some 2,650 feet, the mean annual temperature of which is 73 F. The epidemiologic study made by Dr. Santiago Rengifo demonstrated the presence of Phlebotomus in the region. It is interesting to point out the coexistence of a case of cutaneous leishmaniasis in a young sister of the victim, as well as the frequency of this type of skin lesions in the same district.

A New School of Public Health

The Institute of Hygiene of the University of São Paulo, where a postgraduate course in public health and hygiene was given for several years, has now been transformed into a School of Public Health and Hygiene under the direction of Dr. Paula Souza, who holds a diploma of doctor in public health from the Johns Hopkins University. This is the first university school of the kind to exist in this country. Drs. Borges Vieira, P. Egydio de Carvalho, Alcantara Machado, Alexandre Wancolle, Lucas Assumpção and Arthur A. Whitaker are professors at the new school. Dr. Paula Souza, still absent in the United States, has just served as a member of the delegation of Brazil at the world security conference of San Francisco.

Meeting of Brazilian Ophthalmologists

The twenty-third annual meeting of the Brazilian Society of Ophthalmology will be held at Rio de Janeiro from the 1st to the 6th of September. The principal subjects to be discussed at the meeting are the treatment of ocular syphilis, operation of strabismus, plastic surgery of the orbit, sutures in the operation of cataract, binocular vision in the strabismus and the fundus oculi in the infant. During the meeting Dr. Mendonça Barros of São Paulo will present an extensive report on the present conditions of ophthalmology in the United States, which he recently visited.

Personal

Dr. Hugo Pinheiro Guimarães has been inaugurated as president of the Brazilian College of Surgeons for the year 1945-1946. Dr. Guimarães is professor of surgery at the University of Rio de Janeiro. Dr. Barbosa Vianna, the retiring president, is professor of clinical orthopedics at the same university.

Brief Items

Mr. José Martinelli, a businessman of Rio de Janeiro, has donated a sum corresponding to \$250,000, and a valuable parcel of land, to the Cancer Division of the National Department of Health, in cooperation with the government in the campaign against cancer.

Dr. Deolindo O. Couto has been appointed professor of clinical neurology at the University of Rio de Janeiro. Dr. Couto was formerly associate professor of neurology at the same university and physician of the National Psychiatric Hospital of Rio de Janeiro.

Dr. Emilio Mira y Lopez, professor of neuropsychiatry at the University of Barcelona and director of the Psychotechnic Laboratory of that city, is now at Rio de Janeiro. Invited by the Brazilian government, Dr. Mira y Lopez will give a short course of lectures and practical demonstrations on the myokinetic method of psychodiagnosis. The subjects of some of these lectures will be new directives of psychiatry, mental hygiene of adolescence, some results of the work of the Psychotechnic Laboratory of Barcelona and measurement of aptitudes for vocational guidance. The Spanish physician has been honored by the University of Rio de Janeiro and by the Brazilian Society of Neurology and Psychiatry.

Dr. Beatrice Berle, wife of the American ambassador at Rio de Janeiro and herself a distinguished physician, has given a lecture at the Misericórdia Hospital on the psychosomatic correlation in the diseases of the digestive system, particularly peptic ulcer. The lecture was accompanied by the presentation of some interesting patients by Dr. Figueiredo Mendes.

Several new services have been inaugurated at the Hospital Moncorvo Filho, a municipal institution of Rio de Janeiro: the blood bank, the division of ophthalmology, the division of otorhinolaryngology and the division of necropsies.

An intensive campaign of rural health instruction, conducted by the Division of Health Education of the Special Service of Public Health, has begun in the state of Pará, in the Amazon valley, under the supervision of Dr. Charles Wagley. Several mobile units of moving picture projection are being used.

Dr. Tarquinio Lopes Filho, a practitioner of medicine at Rio de Janeiro since 1909, died recently at the age of 64.

Dr. Alfredo Souza Mendes of Rio de Janeiro died recently at the age of 59.

Marriages

CHARLES LYMAN JORDAN JR., Kinston, N. C., to Miss Florence Fisher Henszey of Philadelphia in Atlanta, Ga., June 23.

JOEL BERNARD HOBERMAN, Arlington, Va., to Miss Sally Winn Chappellear at Braddock Heights, Md., July 4.

RANDOLPH HARRISON HOGE, Richmond, Va., to Miss Florence Irene Elks of Weldon, N. C., June 23.

CHAMPE C. POOL, Charleston, W. Va., to DR. MARJORIE BIRD KISHPAUGH of Hershey, Pa., recently.

RICHARD A. FEWELL, Philadelphia, to Miss Mary White McNeely of Coolemece, N. C., June 20.

FRANK A. McCUE, Bluefield, W. Va., to Lieut. Betty Barron of Watervliet, N. Y., April 20.

STAFFORD L. NORMAN, Coleman, Texas, to Miss Mattie Ellen Hood of Jacksonville, May 15.

MYRON DUANE MATTISON to Miss Elizabeth Milton Weaver, both of Durham, N. C., June 29.

VIRGIL C. HART to Miss Virginia McGunigal, both of Youngstown, Ohio, March 12.

ROY ALLEN HARE to Miss Myrtle Frances Brandon, both of Durham, N. C., June 20.

WILLIAM T. MOSS, Columbia, Mo., to Miss Rose Daily of Kansas City, June 28.

FREDERICK F. GARRISON, Aurora, Ill., to Miss Myrtle Joy in Loami, July 4.

Deaths

Hugh Hampton Young ☉ eminent urologist, died in the Brady Clinic, Johns Hopkins Hospital, Baltimore, August 23, aged 74.

Dr. Young was born in San Antonio, Texas, Sept. 18, 1870. In four years at the University of Virginia he received the A.B., A.M. and M.D. degrees, graduating at the medical school in 1894. He spent the following year in graduate work at the Johns Hopkins Hospital. He then served as bacteriologist and pathologist at the Thomas Wilson Sanatorium, returning to the Johns Hopkins Hospital as intern, assistant resident surgeon and associate in surgery from 1895 to 1914. In 1897 Dr. Young assumed charge of the dispensary of genitourinary diseases at the hospital, launching a long career devoted to this specialty. In 1915 he became director of the newly opened James Buchanan Brady Urological Institute, the gift of "Diamond Jim" Brady, on whom Dr. Young had performed a prostatectomy in 1912.

During his career he held various teaching positions at the Johns Hopkins University School of Medicine, becoming emeritus professor of urology in 1942, the year he retired as director of the Brady Clinic. His scientific achievements include the creation of the perineal prostatectomy, for which he devised special instruments, the radical operation for cancer of the prostate, the invention of the cystoscopic rongeur and an instrument for placing radium in bladder tumors.

Other accomplishments include his successful activities as a citizen. In 1903 he was credited with influencing the passage of bills which had a nationwide effect in the campaign against tuberculosis; he was also active in the creation of the National Institute of Health and as chairman of the Maryland State Lunacy Commission and of the state board of mental hygiene, into which it later developed. Dr. Young was credited with the passage of numerous bills improving the mental hygiene structure of the state.

Dr. Young was a member of numerous scientific groups, serving as president in 1909 of the American Urological Association, of which he was a charter member, and of the American Association of Genito-Urinary Surgeons, in 1912 of the Medical and Chirurgical Faculty of Maryland and in 1917 of the International Congress of Urology. He was secretary of the Section on Genito-Urinary Diseases of the American Medical Association from 1911 to 1913, serving as a member of the House of Delegates in 1910, 1914 and 1926. For years he had been chairman of the Maryland State Aviation Commission and with Governor Ritchie had been active in the selection of sites for airports. He had delivered famous lectures and had received various honors, including the Keyes Gold Medal of the American Association of Genito-Urinary Surgeons and the Amory Prize. A prolific contributor to the literature, he had also written a number of volumes on urology and had been editor of the *Journal of Urology* since he founded it in 1917. In 1940 he published his autobiography. He went to France in 1917 with the American Expeditionary Forces as director of urology, becoming senior consultant the following year. He received the Distinguished Service Medal.

His cultural pursuits were many. Throughout the years he had been at various times vice president of the Baltimore Museum of Art and president of the Baltimore Opera Club, the

Lyric Theater and the War Memorial which served to commemorate Maryland heroes of World War I. The opera club this year presented him with a silver remembrance carrying an inscription of his contributions of time and energy during its twenty-five years' existence. He had been chairman of the Maryland commission of the New York World's Fair and commodore of the Gibson Island Yacht Squadron.

Dr. Hugh Young was the valued friend of many leaders in public life, a physician to several presidents of the United States, a man of boundless drive and dynamic enthusiasm. He gave spirit and leadership to every one of the many activities in which he participated.

Paul Brown Welch ☉ Coral Gables, Fla.; University of Illinois College of Medicine, Chicago, 1913; born in Wauneta, Kan., in 1889; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; interned at the Cook County Hospital in Chicago; formerly an instructor in internal medicine at his alma mater

and an instructor of gynecology and obstetrics at the Rush Medical College in Chicago; on the visiting staff of St. Francis Hospital in Miami Beach; served as chief gastroenterologist at the James M. Jackson Memorial Hospital in Miami, where in 1938 he served as president of the staff and where he died May 6, aged 55, of coronary thrombosis.

Millard Freeman Sewall ☉ Bridgeton, N. J.; Jefferson Medical College of Philadelphia, 1903; born in York, Maine, Sept. 28, 1878; fellow of the American College of Surgeons; served during World War I; formerly an intern at St. Agnes Hospital and resident physician at Girard College, both in Philadelphia; for many years chief of surgical staff at Bridgeton Hospital; past president of the Cumberland County Medical Society and the Tri-County Medical Society; honorary member of Cape May County Medical Society; chief of local emergency defense corps; served on the Selective Service board; died June 4, aged 66, of cerebral hemorrhage and thrombosis.

Thomas Francis Welsh, Salt Lake City; Creighton University School of Medicine, Omaha, 1925; born in Park City, Utah, April 22, 1900, member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology, Western Ophthalmological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; served on the staffs of the Holy Cross and St. Mark's hospitals; consultant at the Veterans Administration Facility; died May 13, aged 45, of coronary occlusion.

Richard Metcalf ☉ Winthrop, Mass.; Tufts College Medical School, Boston, 1913; died May 21, aged 5, of coronary thrombosis.

Mack L. Ross, Topeka, Kan.; Meharry Medical College, Nashville, Tenn., 1913; member of the American Medical Association; on the staffs of St. Francis Hospital and Christ's Hospital, where he died May 21, aged 66, of acute myocardial failure.

George W. Walbright ☉ Metropolis, Ill.; University of Louisville (Ky.) School of Medicine, 1931; coroner of Mascout County; served in the medical corps, Army of the United States, from Dec. 5, 1940 until Feb. 25, 1944, when he was honorably discharged because of physical disqualification; d. l. May 24, aged 37, of coronary thrombosis.

HUGH HAMPTON YOUNG, 1870-1945

DIED WHILE IN MILITARY SERVICE

William Tyson Bower, Philipsburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1942; served an internship at St. Luke's Hospital in Bethlehem; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 3, 1943; assigned to Company C, 93d Medical Gas Treatment Battalion; served in England, France and Belgium, participating in D day operations; promoted to captain; died in Germany April 21, aged 30, of injuries received in a vehicle accident.

Robert Bard Carpenter, Buffalo; University of Buffalo School of Medicine, 1934; interned at the Buffalo City Hospital; served a residency at the Edward J. Meyer Memorial Hospital; an assistant in medicine at his alma mater; entered the medical reserve corps of the U. S. Army as a first lieutenant June 13, 1934; began active duty Nov. 30, 1940 as a captain, promoted to major and lieutenant colonel; commander of the Twelfth Medical Training Battalion at Camp Pickett, Va., where he died Sept. 7, 1943, aged 34, of pulmonary embolism following an operation for an injury received in a fall on a stairway.

William Harold Chain, New Haven, Conn.; Long Island College Hospital, Brooklyn, 1923; formerly an intern at the Buffalo General Hospital in Buffalo and the Hospital of St. Raphael; served in France during World War I; began active duty as a captain in the medical corps, Army of the United States, on June 1, 1942; killed in an automobile accident near Camp Fanning, Texas, Aug. 30, 1943, aged 49.

Clyde Wallace Countryman, Spokane, Wash.; University of Oregon Medical School, Portland, 1924; member of the American Medical Association; interned at the St. Luke's Hospital in Spokane, Bingham Hospital in Bingham Canyon, Utah, and the Salt Lake County Hospital in Salt Lake City; served as secretary-treasurer of the Pacific Northwest Medical Association; began active duty as a major in the medical corps, Army of the United States, on July 5, 1942; later promoted to lieutenant colonel; died in Cuba May 5, aged 44, in an airplane crash.

Joseph Anthony Gadowski, Clinton, Mass.; Boston University School of Medicine, 1943; diplomate of the National Board of Medical Examiners; interned at St. Vincent Hospital in Worcester; began active duty as a first lieutenant in the medical corps, Army of the United States, on Dec. 31, 1943; died in eastern France January 2, aged 29.

Lewis Henry Jannarone, Belleville, N. J.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1939; served internships at the Essex Mountain Sanatorium in Verona and the Jersey City Hospital in Jersey City; began active duty in the medical reserve corps of the U. S. Army as a first lieutenant on Oct. 18, 1941; assigned to Station Hospital in Fort Benning, Ga.; later promoted to captain; died in the Walter Reed General Hospital, Washington, D. C., Oct. 31, 1944, aged 30, of malignant cholangioma.

Philip Joseph Lopresti, Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1941; interned at the Cook County Hospital in Chicago; entered the medical reserve corps of the U. S. Army as a first lieutenant on Aug. 1, 1941; began active duty in the same grade in the medical corps, Army of the United States, on Jan. 16, 1943; assigned to Station Hospital, Westover Field, Chicopee Falls, Mass.; later promoted to captain; died in Italy, February 2, aged 28, in an airplane accident.

Otis Milton Marsh, Minneapolis; University of Minnesota Medical School, Minneapolis, 1941; member of the American Medical Association; interned at the Minneapolis General Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 22, 1942; later promoted to captain; died in the Territory of Hawaii Dec. 24, 1944, aged 30, of pulmonary infarction.

Adolph Edwin Schecter, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1937; served an internship and residency at the Philadelphia General Hospital; assistant instructor in medicine at his

alma mater; began active duty in the medical corps, Army of the United States, as a captain on May 17, 1942; assigned to 20th General Hospital, Camp Claiborne, La.; served in North Africa, Sicily, Sardinia, Italy and France; died aboard ship returning to the United States March 28, aged 31.

Marshall Godfrey Seibel @ St. Louis; University of Louisville (Ky.) School of Medicine, 1929; interned at the New Haven Hospital in New Haven, Conn.; began active duty as a lieutenant commander in the U. S. Naval Reserve on July 29, 1942; died in the Pacific area Sept. 25, 1944, aged 42, of coronary thrombosis.

Charles George Sinclair @ Colonel, M. C., U. S. Army, Radburn, N. J.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1914; in 1916 graduated at the Army Medical School in Washington, D. C., where he had been instructor of pathology and bacteriology; formerly instructor in microbiology and pathology, Army School of Nursing, Washington, D. C.; assistant professor of hygiene at the University of Michigan from 1911 to 1913; entered the medical reserve corps of the U. S. Army as a first lieutenant in August 1915 and the medical corps of the regular army in May 1916; rose through the various ranks to that of colonel; served in the Mexican punitive expedition and World War I; fellow of the American College of Physicians; served as chief in the laboratory service at Walter Reed General Hospital in Washington, D. C.; in charge of Sixth Service Command Laboratory at Fort Sheridan, Ill., and the Tripler General Hospital in Honolulu; an editor of *Biological Abstracts*; author of "Microbiology and Elementary Pathology"; died in the Percy Jones Hospital, Battle Creek, Mich., May 3, aged 55, of carcinoma adenomatousum with multiple metastases.

Eugene Willis Springer, Pontiac, Mich.; University of Michigan Medical School, Ann Arbor, 1936; member of the American Medical Association and the Iowa State Medical Society; interned at the Hurley Hospital in Flint, where he later served a residency in medicine; served a residency in ophthalmology at the University Hospitals, Iowa City; entered the medical reserve corps of the U. S. Army as a first lieutenant on June 20, 1938; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 13, 1942; later promoted to captain; died in Egypt February 23, aged 34.

David Brakenridge Stuart @ Roanoke, Va.; Medical College of Virginia, Richmond, 1924; interned at the Hygeia Hospital in Richmond; formerly on the staff of the Lewis-Gale Hospital; began active duty as a captain in the medical corps, Army of the United States, on July 25, 1942, in charge of a hospital train which evacuated wounded from the western front; went overseas in October 1943; promoted to major; died in Belgium April 14, aged 44, of arteriosclerotic heart disease.

Jehu Creed Walker, Savannah, Tenn.; University of Tennessee College of Medicine, Memphis, 1936; interned at the T. J. Samson Community Hospital in Glasgow, Ky., the Baptist Memorial Hospital in Memphis and the Spartanburg General Hospital in Spartanburg, S. C.; began active duty as a first lieutenant in the medical corps, Army of the United States (National Guard), in January 1941; assigned to Medical Detachment, 149th Infantry, Camp Shelby, Miss.; later promoted to major; flight surgeon with the Eighth Air Force; held the Air Medal and Bronze Star; killed in an aircraft crash in England April 12, aged 31.

Dwight Dunham Young, Santa Ana, Calif.; Columbia University College of Physicians and Surgeons, New York, 1928; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; in charge of obstetrics at the Orange County General Hospital and visiting obstetrician and gynecologist at St. Joseph Hospital, both of Orange; commissioned a lieutenant commander in the medical corps, U. S. Naval Reserve, in March 8, 1942; promoted to commander on Nov. 18, 1942; while in the Pacific, survived the sinking of the U. S. Transport *Little*; died in May, aged 42.

Correspondence

THE RELATION OF EFFORT TO ACUTE ATTACKS OF MYOCARDIAL INFARCTION

To the Editor:—In an article in THE JOURNAL, July 14, entitled "The Relation of Effort to Attacks of Acute Myocardial Infarction," Blumgart has challenged the work of my associates and myself. He believes that in a "small proportion" of cases strenuous exercise may induce coronary occlusion. We believe that in no instance is there any relation.

First one must distinguish clearly between myocardial infarction due to coronary occlusion and that occurring without this complete obstruction. Correct terminology is absolutely essential in discussions of this subject. I take it that Blumgart refers to coronary occlusion, since coronary thrombosis was found in the 4 patients that came to autopsy. In the other seven I am not so sure.

I am well aware that effort may precipitate myocardial infarction without coronary occlusion, induce heart failure and, in fact, cause sudden death. Coronary occlusion is something else again. It is the end result of arteriosclerosis, and no effort, trauma or emotion will produce it.

Blumgart believes that "myocardial infarction" is on the increase in the Army because of strenuous effort that military personnel are called on to perform. The cardiac deaths he reports among men in the Army do not prove his contention, because in civilian life medical examiners find "sudden and unexpected natural deaths" quite common (Helfern, Milton, and Rabson, M. S.: Sudden and Unexpected Natural Death, *New York State J. Med.* 45:1197 [June 1] 1945).

The arguments that appear in Blumgart's paper have been made before. Thus he repeats a paragraph written by Boas to make the point that effort may induce coronary occlusion. Here it is: "The fact that pneumothorax is due usually to pulmonary tuberculosis or to the rupture of an emphysematous bleb does not negate that it may follow trauma to the chest." My reply is simply this: Of course, trauma may cause pneumothorax, but neither pneumothorax nor trauma is under discussion.

Playing baseball, volley ball, running, hiking, marching and engaging in maneuvers, gymnastics and swimming are not necessarily unusual exertion for soldiers. Millions of army men undergo strenuous physical training, and such activities may well have become routine for them. In the eleven short case histories presented, a history of unusual effort is not definitely stated to have been elicited. Only in case 7 is there a suggestion that the run over an obstacle course may have been an unusual physical exertion, but even in this instance there is no statement that this officer had not made the "run" before.

If unusual effort induced coronary occlusion, men and women with coronary sclerosis would sustain this vascular disease daily by the thousands after any extreme effort. This is not so despite the fact that we repeatedly run for a train, move a piece of heavy furniture, pull with unusual effort at a stuck drawer, lift a heavy bundle or suitcase, shove through a crowded subway train or squirm and strain while parking a car in a small space in a crowded thoroughfare. If coronary occlusion were induced by strenuous effort, our life span would be 40 to 50 years, not 60 to 70.

The 11 cases cited in which there appears to be a time association between effort and coronary occlusion are incomplete stories. Although they are inconclusive they influence the reader who may not have an adequate basis of his own for deciding whether strenuous exertion is or is not an immediate

cause of coronary occlusion. He does not know of the hundreds of cases that the cardiologist has had in which coronary occlusion transpired during sleep, rest or mild and usual activity (Master, A. M.; Dack, Simon, and Jaffe, H. L.: Activities Associated with the Onset of Acute Coronary Artery Occlusion, *Am. Heart J.* 18:434 [Oct.] 1939; The Role of Effort, Trauma, Work and Occupation in the Onset and Subsequent Course of Coronary Artery Occlusion, *M. Ann. District of Columbia* 10:79 [March] 1941). In my four years of active service in the Navy I have not seen a single case of coronary occlusion etiologically related to effort.

Sustained and specialized experience leads me to the belief that, even in the rare situation in which there is an apparent time relation between unusual effort and the coronary occlusion, this relationship is not causal but mere coincidence which may be expected in the thousands of attacks of coronary occlusion which take place daily in this country (Master, Jaffe and Dack: The Prevalence of Coronary Artery Occlusion, *New York State J. Med.* 39:1937 [Oct.] 1939).

Let us analyze the 11 cases that are so seriously lacking in detail: "A captain in the Signal Corps, aged 41, collapsed on a hike and was dead at arrival to the hospital." What was the captain's condition before the hike? Isn't it just as logical to assume that he had experienced his coronary occlusion some time before he started his hike as to assume that the hike produced sudden collapse and death? Before important conclusions are drawn much more pertinent information is essential. Only 4 of the 11 patients came to autopsy. The other 7 gave electrocardiograms which were "characteristic." No mention is made of RS-T segment elevations, of Q waves, of reciprocal relationships of leads 1 and 3, so specific for coronary occlusion. Despite our deep respect for the author's professional competence, we must insist that a scientific paper requires more precise data.

As was observed, Blumgart's arguments have been made before. Thus it has been said that since intimal hemorrhages are often observed in coronary occlusion, effort must be the cause. It is asserted that exertion raises blood pressure and this ruptures a subintimal capillary. Is this reasoning any better than concluding that exertion causes red blood cell destruction in the body, a process we ordinarily consider to be physiologically normal? Intimal hemorrhages (Winternitz, M. C.; Thomas, R. M., and Le Compte, P. M.: The Biology of Arteriosclerosis, Springfield, Ill., Charles C Thomas, 1938) are but a part of the process of arteriosclerosis.

Blumgart cites that Henry Horn and L. E. Finkelstein (Arteriosclerosis of the Coronary Arteries and the Mechanism of Their Occlusion, *Am. Heart J.* 19:655 [June] 1940) show that coronary occlusion frequently results from subintimal hemorrhage. However, these authors specifically stated that increased blood pressure following effort played no role in the production of intimal hemorrhage. We have reported intimal hemorrhage at autopsy to be as frequent in coronary disease in patients without hypertension as in those with increased arterial tension (Master, Dack and Jaffe: The Role of Effort, Trauma, Work and Occupation in the Onset and Subsequent Course of Coronary Artery Occlusion). The hemorrhages have been observed just as frequently in patients who have been bedridden for weeks before the coronary occlusion, suffering from cancer, lung trouble and heart failure, as in those who have had high blood pressure and were active before sustaining the coronary occlusion. If more evidence is required that bodily exertion is not a factor in subintimal hemorrhage of coronary sclerosis, I would cite Winternitz's work (Winternitz, Thomas and Le Compte: The Biology of Arteriosclerosis). He injected fluid into the coronary arteries of men whose hearts showed advanced coronary sclerosis under the unheard of pressure of 500 to 1,000 mm. of mercury without producing intimal hemorrhage.

Over a period of years my associates and I have analyzed with utmost care the histories of 1,700 episodes of coronary occlusion and have come to the conclusion that this is an entirely fortuitous end result of progressive coronary arteriosclerosis. It is as frequent in the sedentary as in the physically active. Coronary occlusion is not related to effort, to occupation or to a particular social class. The percentage of attacks which occur during sleep, rest and mild or moderate activity coincides with the proportion of the twenty-four hours usually spent in these respective states. Only 2 per cent of the attacks were related in time to severe exertion. For the reasons given we concluded that the small percentage is expected coincidence. We find support in John Dewey's insistence that a sequence is not necessarily a consequence. But of course a simple attack of angina pectoris and myocardial necrosis without coronary occlusion must be differentiated sharply from the coronary occlusion, and they are induced by effort.

ARTHUR M. MASTER, M.D., St. Albans, L. I., N. Y.
Cardiologist, U. S. Naval Hospital.

NICOTINIC ACID IN VINCENT'S ANGINA

To the Editor:—In *THE JOURNAL*, July 7, are two interesting articles on the use of penicillin in Vincent's angina. From the experience of Captain Schwartz and of Major Shallenberger, Lieutenant Colonel Denny and Major Pyle there is no reason to doubt that penicillin is quite effective in acute cases of Vincent's angina. I am writing, not to question the effectiveness of penicillin, but to suggest that nicotinic acid (or niacin) or nicotinamide has been found by myself and a number of others to be just as effective as penicillin in such cases. Since it is much simpler to take a 50 mg. tablet three times a day than to have an intramuscular injection every three hours for five doses, or even to have penicillin applied locally every four hours, it seems logical to use nicotinic acid first.

So far as I know, J. B. King first called attention to the effectiveness of nicotinic acid in Vincent's disease in the *Lancet* 2:32 (July 13) 1940. For nearly four years I have been using it in all acute cases of Vincent's angina and have found it eminently satisfactory. The dose employed is 50 mg. three times a day for adults; for children, 10 mg. and upward according to age. A week's treatment is usually sufficient. The temperature in all my cases has subsided within forty-eight to seventy-two hours, and the smears have been negative within four to seven days.

WINGATE M. JOHNSON, M.D., Winston-Salem, N. C.

"PSEUDODOXIA PEDIATRICA"

To the Editor:—Your interesting editorial on pseudodoxia pediatrica (*THE JOURNAL*, July 28, p. 955) prompts me to write you that here in Vinton County, Ohio, in the past twelve years I have delivered in homes comparable to those served by the Frontier Service 1,300 babies without a maternal mortality. In this series there were four cesareans done in hospitals, the only ones in the series. The infant mortality is unusually low.

Since the advent of the sulfonamides I have not seen a tympanic membrane go to rupture and have not had a mastoid that required surgery, nor have I done a myringotomy.

Alone down here the past three years it is encouraging to read that we are doing things comparable to other sections, and it is also further evidence that rural communities are in most cases as well off medically as the larger cities.

H. D. CHAMBERLAIN, M.D., McArthur, Ohio.

THERAPEUTIC USE OF ARTIFICIAL RADIOACTIVITY

To the Editor:—During the past several years the artificially produced radioactive elements have become available for use in biologic and medical research as "tracers." So-called tracer doses of these elements, in metabolic studies, are supposedly so small that there is apparently no danger of harm to the organism either immediate or delayed. However, these elements are also being used with success at several centers in this country and abroad by intravenous injection in larger or therapeutic doses for the treatment of certain diseases such as hyperthyroidism (radio iodine), leukemia (radio phosphorus), polycythemia vera (radio phosphorus) and metastatic bone tumors (radio strontium). Some workers, after a short experience in the therapeutic use of these substances, have become a bit too enthusiastic regarding their value. As far as I am aware, no "cures" have been accomplished. The immediate dangerous possibilities of any form of irradiation (x-rays, gamma rays, radium, artificial radioactivity) are well known to most physicians, but in addition there are possible delayed effects. Cases of aplastic anemia and osteogenic sarcomas have developed after many years among radium dial painters, and it is possible to induce delayed neoplastic change in animals by roentgen or other forms of irradiation. Thus, such larger doses can be harmful. However, in the hands of experienced personnel these dangers can be appreciated and damaging effects avoided. Consequently the therapeutic use of artificial radioactivity must be carefully controlled with these dangers constantly kept in mind. It should be stated that so far there has been no definite evidence of any of these delayed effects as far as I am aware, but these possible complications should always be kept in mind in deciding whether a radio element should be used in therapy. It is this point which I wish to emphasize.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Lung Abscess Caused by Bacteroides Necrophorus.—

Spontaneous infections with Bacteroides necrophorus occurring in domestic animals and birds producing an acute type of necrotizing inflammation of the mucous membranes, skin, lungs and liver are well known to veterinarians, but human infections with this organism are rare. Callahan and his associates report a case of lung abscess in a man whose occupation of wool and fur buyer brought him in contact with green hides of cattle and sheep, which was possibly the source of infection. The history of a sore throat, which subsequently disappeared, followed by signs of pulmonary disease and the subsequent development of a lung abscess, lends strength to the idea that the infection was air borne. The absence of lesions on the surface of the body plus a history of sore throat and the finding of a purulent exudate on the inflamed tonsils suggests that this was the port of entry of the organism into the body. The mechanism of the formation of the abscess in the lower lobe of the right lung was probably the aspiration of infected material. The disease process was confined to the respiratory system and there was an attempt on the part of the host to heal the infection by the formation of a dense wall of fibrous tissue around the abscess cavity. Rupture of the abscess into a bronchus occurred, with

spread of infection to other lobes of the lungs. A gram-negative, pleomorphic rod with filamentous and coccobacillary forms was isolated from the pulmonary lesions at necropsy. This organism was an anaerobe. Pathogenicity for rabbits, guinea pigs and mice was demonstrated. A rabbit was hyperimmunized with a known strain of Bacterium necrophorum and the obtained serum agglutinated the recovered organism in dilutions of 1:320 and the specific antigen in dilutions of 1:640. On this evidence the organism was classified as Bacteroides necrophorus. Infections with Bacteroides necrophorus are probably more common than previously supposed.

Nontuberculous Lung Abscesses in Children.—Of 417 cases of lung abscess reviewed by D'Ingianni 64 occurred in children aged 13 years or younger. Etiologic factors in these 64 cases included pneumonia, tonsillectomy, otitis media, whooping cough, aspiration of mucus or of a peanut, diphtheria and the like. The abscesses were most frequent on the right side and in the lower lobes. Sixteen of the patients had multiple abscesses, and 14 of these died. Of the 42 with single abscess 11 died, 10 remained unimproved and 21 were improved. In the remaining 6 it was not stated whether the lesion was single or multiple. The treatment was chiefly symptomatic; only 3 patients received surgical treatment. Of these 1 died. Of the 8 treated with sulfanilamide 5 died. The mortality rate for the entire group was 40.6 per cent. The high mortality indicates that palliative therapy is inadequate. The rigid cavity, with tissues fixed to a bony wall by adhesions, and the fibrous tissue in the bronchi form a rigid fibrous mass about the abscess. Extirpation of the diseased tissue seems a more feasible therapy.

Shock in Acute Infections.—Warren and his co-workers discuss the form of shock that occurs with acute infections. This syndrome is manifested by apathy, cold clammy skin, shallow respirations, a thready rapid pulse and low blood pressure. Shock of the so-called secondary type, or what may be better termed "cold shock," during the course of acute infection is due to failure of the peripheral circulation with pooling of the blood in the capillaries. The authors report 3 cases typical of the therapeutic problems presented by three serious infections. The first case was one of severely toxic scarlet fever. The temperature and some of its toxic manifestations were controlled by intravenous administration of pooled convalescent scarlet fever serum. However, the tone of the vascular system did not return until the fourth day, and during that time intravenous fluid and plasma were necessary to maintain the blood

pressure at a critical level. The second case was a fulminating meningococcemia with a massive invasion of the blood stream by bacteria and bacterial products. Many of these patients die in severe shock before the infection can be controlled by chemotherapy. In this case it was possible by the use of intravenous fluid and plasma to maintain the circulating blood volume and blood pressure at a critical level until the infection could be controlled by sulfadiazine. In the third case, one of type III pneumococcal pneumonia, the circulating blood volume was maintained by intravenous plasma and fluids while the infection was being treated with sulfadiazine and type III antiserum. The institution of specific measures to combat the infection is of primary importance, since they are directed at the cause of the shock state. Death in the early stages of acute fulminating infections may occur as a result of secondary shock. If vigorous antishock therapy directed to maintain an adequate circulating blood volume is resorted to, many patients may be maintained until specific serum or chemotherapy or both have been able to control the infection.

Herpes Zoster and Varicella.—A woman aged 81 visited and cared for a small boy who had just recovered from chickenpox. She held the boy on her lap and read to him for several hours. She noticed that the child still had conjunctival irritation and photophobia. Six days later the woman developed a painful red area on the right side of her forehead and two days later she had a typical herpes zoster lesion involving the right supraorbital region. There was some conjunctival injection, a slight cloudiness of the cornea and a very slight ciliary injection. Pain disappeared in five days. The woman had never had chickenpox. Kern suggests that doctors treating either disease should warn those close to the patient of the infectious nature and point out to older persons the danger of contracting herpes zoster after exposure to chickenpox.

*Pregnancy in the Diabetic. L. J. Palmer and R. H. Barnes—p. 195
*Results of Convulsive Shock in Approximately 1,000 Patients. P. S. Wolfe.—p. 203.

Pregnancy and Diabetes.—Palmer and Barnes discuss 68 pregnancies occurring in 41 diabetic women treated at the Mason Clinic during the fourteen years previous to June 1944. The majority of the observations were made during the past six years. Thirty-seven of the pregnancies terminated under their care and 31 terminated elsewhere. Among the 37 pregnancies there were 26 fetuses which reached the age of viability, and there were 22 living children. This number represents 60 per cent of the 37 pregnancies terminated under their care, and 84.6 per cent of these pregnancies which reached the age of viability. Eleven of the 37 pregnancies terminated spontaneously or were terminated intentionally before viability. The authors think that unless future use of substitution endocrine therapy changes the present situation, cesarean section at the thirty-sixth week will be the method of delivery which will produce the highest percentage of fetal survival. They stress that the very wide variation in the percentage of fetal survival is not totally explained by a difference in the manner in which the pregnancy and the diabetes were conducted. There are deeper and more fundamental reasons, and they emphasize that the greatest fetal and maternal (especially the former) risk occurs in the juvenile diabetic patient. Cerebral anoxemia frequently due to edema is the commonest cause of neonatal death, which is related directly to the diabetes. Control of the diabetes during pregnancy is usually relatively simple but must, if possible, be guided by frequent blood sugar determinations. Hormonal imbalance is rapidly becoming recognized as the most common cause of high fetal mortality and maternal morbidity. This imbalance is present in 60 to 70 per cent of pregnant diabetic women.

Results of Convulsive Shock.—Wolfe reports experiences in treating 1,021 patients over a six year period. These patients received a total of 1,313 courses and 11,104 individual shock treatments. Metrazol was used in 4,430 and electric shock in 6,674 treatments. Metrazol has been supplanted largely by electric shock because of its economy and convenience of administration, but there are occasional instances in which metrazol is still preferred. In selecting cases for treatment it is best to avoid those of long standing, and the affective reaction types are preferred to the schizophrenic patients. Many mental illnesses featured by depression respond well to convulsive shock therapy. Behavior problems in chronic psychiatric illness can be improved with shock therapy. It is desirable to try more conservative methods of management before resorting to shock treatment. Prolonged courses of about fifteen seizures are suggested for schizophrenic patients and for the manic patients who are slow to show improvement. For the sluggish schizophrenic patients, metrazol is more effective than electric shock. After shock treatment an observation period of at least two weeks is advised in which time psychotherapy is most effective, and in this period occupational and recreational therapies can be arranged. If a relapse is going to occur, it usually appears during this time. In manic patients a month of observation with a nonstimulatory regimen will prevent some relapses. Repetition of treatment following a relapse is worth consideration in manic depressive psychosis, especially in the depressive type, but it is of questionable value in schizophrenia. The cardiovascular system must be carefully evaluated for cardiac reserve and for evidence of toxic myocarditis before deciding to administer shock. Phlebitis, even if resolving, is a contraindication to treatment. The death rate in this series was 0.49 per cent. The results were best in the affective reaction types, the depressed manic patients responding even better than the manic types; in those with involutional depression and with senile depression the results were fairly good, while in those with schizophrenia with involutional paranoia and with psychoneurosis they were disappointing. Curare is a valuable aid in preventing fractures and dislocations, in allowing treatment in otherwise too risky patients, and it presents little additional hazard, especially if the antidote, neostigmine, is kept at hand.

 Congenital Malformation of Heart in One of Identical Twins. Kathleen McClintock.—p. 47.

Prophylaxis and Treatment of Rickets.—Krestin discusses the results of the routine administration of cod liver oil containing from 600 to 800 international units of vitamin D to the drachm (4 cc.), for the protection against rickets, and of this oil and a more concentrated preparation of vitamin D for infants with active rickets. In a series of controls under 12 months of age receiving no protective vitamin, two thirds developed rickets, whereas in a similar series between 1 and 2 years only 10.7 per cent developed the disorder. Control children over 2 years all remained free during the six months of observation. A daily dose of 1 drachm of cod liver oil (600 to 800 international units) failed to protect two thirds of infants under 6 months. Two drachms, or 1,500 international units, protected most and 3 drachms, or 2,100 international units, all infants under 1 year. About 11 per cent of infants between 1 and 2 years receiving 1,500 international units daily developed rickets, but all remained free on 3,000 international units. Infants under 1 year showing mildly active rickets were cured on 1,500 units of cod liver oil daily. Those between 1 and 3 years appeared to require doses up to 3,000 units. All infants showing severe rickets responded well to daily doses of 3,250 units in a concentrated preparation.

Paroxysmal Tachycardia in Infancy.—Leys presents the report of a girl baby who was hospitalized two months after birth because two days before she had been discovered in her cot looking "suffocated." She was red in the face, sweating and gasping for breath. After two hours she improved but later vomited her food. Subsequently she appeared to have spasms of pain and was restless all night and the following day; breathing was labored. The heart rate was found to be 240, with regular rhythm. The cardiogram showed auricular tachycardia. Chloral hydrate was given and, because an infection was suspected, sulfadiazine. The cardiac condition improved but signs of encephalopathy appeared and the child died. Lydia Fehily described a syndrome characterized by vomiting, abdominal pain, diarrhea, abdominal distention, stiffness of the neck and extremities and convulsions. She suggested that this syndrome is due to milk intoxication from mothers with beriberi. Leys has seen at least one attack of this kind in a breast fed infant. The resemblance between the two types of syndrome, (1) Fehily's infantile intoxication and (2) the syndrome of tachycardia with fever, leukocytosis and symptoms suggestive of encephalopathy, suggests a common cause, such as milk intoxication.

- *Cystometry. D. Band.—p. 1.

Cystometry.—Cystometry is a recent addition to methods of urologic examination. It implies a urologic examination of a spinal cord reflex. The bladder is a reflex organ, and the stimulus to contraction is the "stretch reflex" of the bladder

musculature. A technic for cystometry has been devised whereby the "stretch reflex" of the bladder may be studied as a kymographic recording of the bladder contractions. The normal cystogram is described and a classification is suggested for the various types of neurogenic bladder. Typical case neurogenic bladder illustrate the conformity of the cystometric interpretations of the neurologic symptoms and signs.

 Treatment of Soft Warts with Podophyllin. J. V. Macgregor.—p. 59.

Intravenous Arsenic in Glandular Fever.—According to Smith and Shaw, throat lesions of the anginous type of glandular fever may be among the most severe that can be encountered. Not only may there be massive edema accompanying the acute inflammation of the tonsils and neighboring structures, but these may become extensively ulcerated; considerable bleeding may ensue. Bronchopneumonia may develop and bring about a fatal issue. The authors employed nearsphenamine in the first case with the aim of countering a Vincent's infection which was believed to be complicating anginous glandular fever. The beneficial effect of the drug in this case prompted its use in cases 2 and 3 even though no Vincent's organisms had been found in the throats. In both rapid subjective and clinical improvement resulted, and similar results followed this therapy in the remaining cases. The immediate improvement in the local and general condition of the 6 cases and the subjective improvement indicate that the arsenical was beneficial. Nearsphenamine was given intravenously in doses of from 0.15 to 0.45 Gm. Local treatment is also important in anginous forms of glandular fever. Scrupulous attention to cleansing of the throat, teeth and gums is the first essential. Swabbing with hydrogen peroxide was the most effective local treatment in the acute stage, while applications of hot absorbent cotton or kaolin eased the pain in the neck. After the acute stage, and for residual ulceration of the tonsils, a paint made up of equal parts of liquor arsenicalis and tinctura ipecacuanhae was the most effective local application.

Development of Anti-Rh Agglutinins After Multiple Transfusions of Rh Positive Blood to Rh Negative Patient.—Drummond and his associates report results of multiple blood transfusions given a woman aged 47 with suspected thrombocytopenia. The Rh blood group was not ascertained. Five of the 6 donors used for the first three transfusions were Rh positive, while the Rh group of the sixth one was not known. The first diagnosis of Rh positivity was made on the third day after the third transfusion and was due to large numbers of surviving cells of the Rh+ donors in the recipient's blood. The next three transfusions were not complicated by febrile reactions although 2 at least of the 6 donors used were Rh+ and no incompatibility was observed in the cross matching tests. The reaction complicating the third transfusion was possibly hemolytic in nature, since there was no subsequent rise of hemoglobin. Hemolytic reactions complicated the seventh, eighth, ninth and tenth transfusions. The significance of these reactions was not at first apparent. Only in retrospect did the position become clear. It was because of the reaction and the agglutination observed in the cross matching tests in the tenth transfusion, and the failure of the patient to improve despite transfusions, that further investigations were requested. Only when the Rh negative diagnosis was made and the anti-Rh agglutinin discovered in the recipient's serum was the history reviewed and the facts placed in their true perspective. This case illustrates the importance of (1) ascertaining the Rh group of a recipient as a preliminary when multiple blood transfusions are contemplated, (2) the possible danger of being misled when an Rh negative recipient's blood gives an Rh+ reading after a blood transfusion and (3) never omitting cross matching tests.

- *Arterial Hypertension Modern Conceptions E. Cruz Coke—p. 154

Arterial Hypertension.—Cruz Coke established in animal experiments that hypertensin (angiotonin) and hypophysin are destroyed in vitro by the addition of pure iodine. The addition of cytochrome oxidase to a mixture of isotonic solution of three chlorides and hypertensin nullified the hypertensive effect of hypertensin during perfusion, and intravenous or intraperitoneal injection of cytochrome oxidase to animals with experimental hypertension produced either normalization of arterial blood pressure or a decided lowering. The hypotensive effect lasted for more than sixteen hours. In normal animals the injection of cytochrome oxidase did not affect the blood pressure. The author concludes that arterial hypertension is due to diminished respiration of tissues, which in turn stimulates production of hypertensin and slows destruction of this substance. Hypertensin and hypophysin are both hypertensive substances which can be destroyed by oxidation. The treatment of hypertension aims to restrict rather than to prevent the formation of hypertensive substances. It consists in administration of cytochrome oxidase and of catalyzers of oxidation. Food rich in tyrosine and in proteins is prohibited.

- Free Transplant of Full Thickness Graft T. M. Khitrov—p. 31.
- *Extraperitoneal Lumbar Sympathectomy for Causalgia P. S. Babitskiy—p. 34.

Tissue Therapy of Indolent Wounds.—Berdichevskiy reports 150 observations in which tissue therapy was resorted to in order to stimulate the healing of indolent wounds. Both homoplastic and heteroplastic tissues were used. All of the tissues proved effective. That taken from a thyrotoxic thyroid and fat tissue appeared to provoke a greater reaction. The tissue is kept for use in 0.5 per cent solution of phenol. More recently the author resorted to placental and amniotic tissue. The tissue is applied directly to the wound without any particular treatment of the wound or the ulcer. In the treatment

of trophic ulcers there were 25 per cent failures. The tissue applied to the wound does not suppurate; it undergoes lysis. The changes in the wound consist of rapid granulation and rapid epithelization.

Sympathectomy in Causalgia.—Babitskiy states that sympathectomy gives an early and permanent relief from causalgia. Causalgia of a lower extremity is best treated by the removal of the fourth, third and possibly second lumbar ganglia. Removal of the stellate ganglion and third dorsal is indicated in the causalgia of the upper extremity. In some cases more or less permanent relief was obtained by procaine hydrochloride blocking of the corresponding sympathetic ganglia.

- Thrombosis Following Leg Injuries G. Bauer—p. 229
- Delayed Cholangiography and Treatment of Overlooked Stones by the Pribram Method T. C. Gertz—p. 249

Urinary Lithiasis in Childhood.—The material presented by Winkel Smith comprises 71 cases of urinary calculi in children up to the age of 14. The ratio of boys to girls was 3 to 1. The duration of symptoms before the diagnosis indicates that two thirds presumably have had the stones before the age of 5. The greatest majority of these children had either renal or ureteral stones, only a few had vesical and urethral calculi. Spontaneous passage of stones was observed in 26 cases, and in 12 of these there was no recurrence. Fifty-three of the patients underwent 63 operations. Primary nephrectomy was done in 7 cases, simple lithotomy in 36, and 9 of the patients were subjected to several operations. There was one surgical fatality. The recurrence percentage was 29 in infected and 11 in aseptic cases. Urinary lithiasis in childhood is not as rare as is generally assumed in the Scandinavian countries. Surgical intervention is advisable irrespective of age, because considerable damage to the urinary tract is likely to result.

- Sex Education in Schools C. W. Herlitz—p. 1244.

Poliomyelitis Epidemiology.—Olin reports that in the 8,288 with paralysis of 9,992 poliomyelitis cases in Sweden from 1930 to 1939 the mortality was 15.6 per cent. The morbidity was about 25 per cent higher in men than in women. The greater morbidity in predominantly agricultural communities depends mainly on greater morbidity in the age groups over 10. Increased resistance is believed to depend on latent immunization, which affects different categories of population in varying degrees.

Pure Preparation of Poliomyelitis Viruses.—Gard describes the successful purification by salting out and differential centrifugation of murine and human virus proteins and isolation from human stools and the intestinal contents of mice of protein substances which are similar to the neurovirus protein. No essential differences between the neurovirus and the intestinal virus or between active and inactive material from the intestinal contents could be established in study of the morphology of the preparations by electron microscopy.

Book Notices

Food for the World. Edited by Theodore W. Schultz. Cloth. Price, \$3.75. Pp. 353, with 8 illustrations. Chicago: University of Chicago Press; London: Cambridge University Press, 1945.

This book is not one person's views but a compilation of essays by twenty-two qualified authors followed by discussions. The material was presented at the twentieth institute of the Harris Foundation of the University of Chicago.

The six parts of the book are devoted to the food movement, population, nutrition, food supplies, international relations and consequences and policy. The arrangement is logical, and the general index is a further aid to the interested reader to find what he wants in this broad field. Even in countries that have an abundance of food, the diets of large sections of the population for the most part run counter to the knowledge and experience of present day advances in nutrition science and medical science. The war, with its extensive destruction of agricultural areas, farm equipment and transportation, and displacement of millions of people made peacetime unsatisfactory conditions even worse.

As far back as 1930 the League of Nations through its Mixed Committee laid the foundation for the movement for better food and nutrition as a public health measure. The work of the league had not advanced far enough and had not received the encouragement it deserved when the present war broke out. The matter of food was again brought to the world's attention at the conference on food and agriculture at Hot Springs in 1943 and presumably will not be missing from the deliberations by a suitable section of the several councils provided by the charter of the recently held San Francisco United Nations Security Conference. Governmental and voluntary international and national organizations again face the challenge of feeding those in the world who are hungry and furnishing the whole world with the kind of food that has the essential nutrients.

Some of the essays review the ever growing concern with food and nutrition. They describe the advances made in these fields and their relationship to health. They point out the population problems, rises and declines as caused by mortality, fertility and other factors, and ratios of populations to land. Attention is called to the estimate that more than one half of the world's two billion people are underfed. The essays deal with food consumption levels as influenced by the income of the individual or family, by the price of food, by degree of popular knowledge as to intelligent selection of food and by the supply of food in places where it is needed. In several places reference is made to agricultural surpluses in the past in the United States and the measures of government aiming at their balance. The point is well made that even abundance of food supply is adequate only when it contains the essential nutrients, and this aspect is important to any intelligently conceived and soundly applied food program.

The discussion on the advances already made in nutrition research only strengthens the need for continuation and extension of investigational projects not alone with animals but also with human beings. The areas that especially require intensive study are the vitamins and minerals.

Total War and the Human Mind: A Psychologist's Experiences in Occupied Holland. By Major A. M. Meerloo, M.D., F.R.S.M. Cloth. Price, \$1.75. Pp. 78. New York: International Universities Press, Inc., 1945.

The name of Major Meerloo is known to the medical profession as that of a competent psychologist and physician. He has written previously on such subjects as the psychology of pain and sorrow. For more than two years he lived under the German oppression. The story of life in Holland during those two years is a convincing personal narrative of that experience with the philosophical comment of a trained observer. He has analyzed Hitler's psychologic weapons and the morale that enabled the Dutch people to resist. A section on the psychology of radio propaganda should be studied by every one interested in the use of the radio as a tool for mass education. His prophylaxis for the next war bids fair to be realized in the new San Francisco charter. Coupled with such an international mechanism, he calls for active education in democracy.

Population Roads to Peace or War. By Guy Irving Birch, Director, Population Reference Bureau, and Elmer Pendell, Ph.D. Foreword and Postscript by Walter B. Ptkin, Ph.D. Paper. Price, \$1. Pp. 138. Washington, D. C.: Population Reference Bureau, 1945.

The main thesis of this book is that the differential fertility and mortality throughout the world is a force of great weight in the determination of economic, political and international policy both in peace and in war. The facts on which the book is based are well known to students of demography and have been publicized more widely to the general public in recent years. The authors are well qualified by previous experience in the field. The book is written for the intelligent layman and could be readily understood by him. The increase of 50 million in the population of India between 1930 and 1940 is one of those facts. The book discusses widely held fallacies about population, including the role actual and potential of migrations, sterilization and marriage standards. The principal conclusion is that satisfactory standards of living in peacetime cannot be effected without population limitation and that unless such measures become more widespread, especially in certain critical areas of the world, all attempts at international organization to prevent war inevitably will fail. The population facts as given in the booklet are based on the best available information; the conclusions and recommendations represent opinions held by the authors and by many other well informed persons. Whether or not all of them will stand the test of critical evaluation and of time remains to be determined, but they deserve the attention of all thoughtful citizens.

Physical Growth from Birth to Two Years. I: Stature. A Review and Synthesis of North American Research for the Period 1850-1941 [Including Appendix of 23 Tables]. By Howard V. Meredith, Ph.D., Robert R. Sears, Ph.D., editor, University of Iowa Studies, Studies in Child Welfare, Volume XIX, No. 407. Paper. Price, \$1.50. Pp. 255. Iowa City: University of Iowa Press, 1943.

This monograph presents much accurate information scientifically gathered which should be interesting and informative to the pediatrician as well as to the research investigator. The many authoritative abstracts on the relation of diet, disease and various physical abnormalities to stature makes a valuable treatise. The extensive bibliography should be very useful to any one undertaking such studies in the future on the differences and the effects of illness and dietary treatment. Part II is an annotated bibliography of all studies published in North America to 1942 and gives data on stature during the first two years of life. It represents much more work than its size first suggests and would make a valuable reference work for any one interested in infant development.

National Health Agencies: A Survey with Especial Reference to Voluntary Associations. By Harold M. Carvins. Including a detailed directory of major health organizations. Cloth. Price, \$3. Pp. 251. Washington, D. C.: Public Affairs Press, American Council on Public Affairs, 1945.

Here is a record of the various voluntary public health agencies in the United States with information concerning their histories, backgrounds and place in our social organization. The national society of medical origin in the United States with the longest continued existence is the American Psychiatric Association, organized in 1844; next is the American Medical Association in 1847. The three chapters on the basic characteristics, backgrounds and social awakening related to voluntary public health organizations are most interesting. The discussions are succinct and yet fully informative. The book constitutes one of the best references thus far available in the field it concerns.

Jurisprudence for Nurses: Legal Knowledge Bearing Upon Acts and Relationships Involved in the Practice of Nursing. By Carl Scheffel, Ph.B., M.D., LL.B., in collaboration with Eleanor McGarrath, R.N. Third edition. Cloth. Price, \$3. Pp. 264. New York: Lakeside Publishing Company, 1945.

This is the third edition of a book originally published in 1931. It contains seven chapters dealing with the legal status of nurses, the legal obligation of nurses, nurses and contracts, nurses and wills, nurses as witnesses, criminal responsibility of nurses and property rights in clinical charts, case histories, roentgenograms, certain other records and pathologic specimens. A brief analysis of the nursing laws of the United States and Canada is included in an appendix.

Organic Chemistry. By Louis F. Fieser and Mary Fieser. Cloth. Price, \$8. Pp. 1,091, with illustrations. Boston: D. C. Heath & Company, 1944.

This textbook of organic chemistry is one of the best such fundamental works of recent years and follows generally the traditional plan of organization. The book has special features in the addition of numerous optional chapters, written mostly by Mary Fieser, on applications of organic chemistry to technology and to the biologic and medical sciences, rendering the book particularly valuable to the physician. It thus affords the pre-medical student the chance to get a glimpse of the direct application of this phase of chemistry to his interests. A few of the supplementary topics are microbiologic processes, role of carbohydrate in biologic processes, metabolism of fats, proteins and amino acids and advances in chemotherapy. In view of the present day lack of good biologic chemistry textbooks, these sections are particularly valuable in presenting briefly current knowledge of certain phases of metabolism. The book is particularly well written and contains more than the usual number of structural formulas, structural equations and tables of constants of compounds. One criticism of the manuscript may be leveled at the incidental treatment of the heterocyclic compounds. However, extensive references at the end of each chapter and an adequate index complete an otherwise well rounded textbook.

Public Medical Care: Principles and Problems. By Franz Goldmann, M.D. Cloth. Price, \$2.75. Pp. 226. New York: Columbia University Press, 1945.

The author discusses the development of hospitals, medical centers and plans for the care of the indigent. He considers finally programs of planning for expansion of medical institutions and services, inclining actually toward a complete system of state medicine but being willing apparently to concede that physicians are people. He states that there are three ways to solve the problem of medical care: (1) centralization of both power and function, (2) decentralization of both power and function and (3) centralization of power, complete or limited, along with decentralization of function or certain types of function. The approach of Dr. Goldmann, although he is a physician, is distinctly that of the economist and social worker. There seems to be nothing in his point of view which would mark it particularly as that of the man trained in the American tradition of democracy.

Personnel Work in Schools of Nursing. By Frances Oralind Triggs, Ph.D. Cloth. Price, \$2.75. Pp. 237. Philadelphia & London: W. B. Saunders Company, 1945.

This has been prepared as a guide for the development of student personnel programs in schools of nursing education. Its primary purpose, therefore, is to instill in the prospective counselor, the teacher, the supervisor and other members of the administrative nursing staff a greater knowledge and understanding of the problems, techniques and methods involved in the guidance and counseling of students in training. The book is divided into four parts, including a brief introductory review of the structural, physiologic and psychologic bases of human behavior, learning and adjustment. The remaining sections are devoted to the counseling program itself, which the author has handled with expert knowledge. Part II describes the essential qualifications of counselors, individual techniques and many of the nursing problems that are commonly encountered in educational, personal and vocational counseling. In part III the reader becomes familiar with the various methods employed in the selection of students as well as the interpretation and evaluation of individual tests. By presenting a complete case record in part IV the author has successfully illustrated many of the principles and technical details involved in the counseling process. An extensive bibliography provides ready access to other valuable references in this field.

LeRoy Long: Teacher of Medicine. By Basil A. Hayes. Fabrikold. Price, \$1.50. Pp. 91, with 4 illustrations. Oklahoma City: The Author, 1943.

This work includes a series of articles previously published in the *Journal of the Oklahoma Historical Society*. It traces the life of a medical pioneer of our own times who fought for high standards of medical care and who contributed greatly to the advancement of medicine and medical education in Oklahoma.

The Basis of Clinical Neurology: The Anatomy and Physiology of the Nervous System in Their Application to Clinical Neurology. By Samuel Brock, M.D., Professor of Neurology, College of Medicine, New York University, New York. Second edition. Cloth. Price, \$5.50. Pp. 393, with 72 illustrations. Baltimore: Williams & Wilkins Company, 1945.

This has proved its value and established its position in American neurologic literature since it first appeared in 1937. This work correlates the facts of neuroanatomy and neurophysiology with the clinical manifestations of neurologic disease in a useful fashion. It bridges the gap between laboratory studies and the bedside for both student and practitioner. In the new edition the author has surveyed and analyzed the literature and has brought to his readers in a clear and concise fashion the recent advances in fundamental science. There are but few statements to which exception can be taken. The book can be recommended to all who wish to bring themselves up to date on important matters of neuroanatomy and neurophysiology and their relation to the behavior of the human nervous system in both health and disease.

The American Year Book: A Record of Events and Progress, Year 1944. Edited by William M. Schuyler with the cooperation of a supervisory board representing national learned societies. Cloth. Price, \$12. Pp. 1,082. New York: Thomas Nelson & Sons, 1945.

This book presents a survey of the year 1944 in twenty-seven major fields of activity, among them the medical sciences. The reviews of medicine, pathology and physiology are prepared by Dr. Max Trubek of New York, who tells of the advances with penicillin, the control of typhus, the insect repellents, thiouracil and blood fractions. The article on surgery is by Dr. Edwin J. Pulaski of New York. He discusses the sulfonamides, penicillin, proteins, thiouracil, frostbite and blood fractions. The article on public health is by W. W. Peter of New Haven, Conn. He discusses the health of the nation from many different points of view and seems to have reviewed adequately major fields of interest in public health in recent years.

François Magendie: Pioneer in Experimental Physiology and Scientific Medicine in XIX Century France. By J. M. D. Olmsted, Professor of Physiology, University of California, Berkeley, California. With a preface by John F. Fulton. Cloth. Price, \$5. Pp. 290, with 5 illustrations. New York: Schuman's, -1944.

This is a clearly written factual account of a great pioneer in the medical sciences of France a hundred years ago. The first part of the last century was a great period for medical science in that country, with such leaders as Lavoisier, Magendie and Magendie's pupil Claude Bernard. It is worth while for members of our profession to secure inspiration, guidance and courage from the great medical leaders of the past, men who frequently labored under great difficulties and yet carried the torch forward. Professor Olmsted has rendered medicine a distinct service in presenting this clear story of François Magendie.

The Autobiography of Science. Edited by Forest Ray Moulton and Justus J. Schifferes. Cloth. Price, \$4. Pp. 666. Garden City, N. Y.: Doubleday, Doran and Company, Inc., 1945.

For every physician this anthology will be an interesting and useful work. Here are quotations from most of the important scientific works known to mankind, with brief introductory biographic statements and with interpretative paragraphs that add to their value. The work begins with the story of creation from Genesis and carries us along through the Smith Papyrus and the works of Hippocrates to Sigmund Freud, William Osler, Walter Cannon and Harvey Cushing.

Taber's Dictionary of Gynecology and Obstetrics. By Clarence Wilbur Taber. With the collaboration of Mario A. Castallo, M.D., F.A.C.S., Assistant Professor of Obstetrics, Jefferson Medical College, Philadelphia. Cloth. Price, \$3.50. Various pagination, with illustrations. Philadelphia: F. A. Davis Company, 1944.

The authors in their foreword say that this is a specialized medical dictionary designed for all those interested in obstetrics and gynecology, the nurse, student, practitioner and specialist. In addition to the usual definitions, many subjects are treated in considerable detail with the aid of outlines and illustrations. Some data, such as an outline of infectious diseases in children, are not quite pertinent to the subject. Some common terms are absent. Ergot is defined, but ergonovine is missing. This small book may be a useful reference book, but it does not replace the standard medical dictionaries.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ENDOCRINES FOR HYPOGONADISM AND THE MALE CLIMACTERIC

To the Editor:—What is the danger, if any, of effecting testicular atrophy or germinal cell depression with the use of testosterone (testosterone propionate and methyl testosterone) or pituitary gonadotropin in such conditions as hypogonadism, cryptorchism and the male climacteric? Are such changes, if any, irreversible? Are there any other possible contraindications? Of the two substances testosterone and gonadotropin, which is preferable in the treatment of the conditions mentioned?

M.D., California.

ANSWER.—In a man with a normal spermatozoa count the administration of testosterone propionate in a dose of 25 mg. a day may produce azoospermia. Recovery takes place within two to three weeks after discontinuing treatment, and there are apparently no ill effects. It is not known definitely whether methyl testosterone will produce the same effect or not. Azoospermia also has been produced in a few instances by the administration of pituitary gonadotropin. The best general rule to follow in the treatment of hypogonadism is to use stimulation therapy first and to resort to substitution therapy with male sex hormone if it fails. Commercial preparations of pituitary gonadotropin are of little value in men. They sometimes produce menstruation in women with secondary amenorrhea. Chorionic gonadotropin is effective in men. It stimulates the interstitial cells of the testis to produce male sex hormone but has little or no influence on spermatogenesis. It is primarily of value in the treatment of cryptorchism and hypogonadism secondary to hypopituitarism. It is also of value in the Froehlich syndrome. Testosterone propionate is more effective in the male climacteric.

SCLERODERMA AND ULCERATION OF LEGS

To the Editor:—For about two years I have been treating a woman aged 58 for scleroderma with deep ulcerations of both legs. I have used thyroid and mild ointments. The ulcers have healed except for two spots and superficial skin lesions. Would it be advisable to try penicillin?

Theodore Bilski, M.D., Westfield, Mass.

ANSWER.—Ulcers seldom form at sclerodermatous sites, except at bony prominences or where there is extrusion of associated calcium deposits. Scleroderma of the legs usually develops a hidebound condition, which over the legs is severe. If the lesions really were sclerodermatous, it is probable that they were of the morphea variety. This is so because the latter finally develops a thin atrophy and in this patient the remaining lesions are superficial. Several conditions on the legs may stimulate scleroderma or localize scleroderma. Necrobiosis lipoidica diabetorum may or may not ulcerate. A dermatitis on the legs due to insufficiency in the circulation may sometimes be quite indurated and thickened to simulate scleroderma. Such a stasis dermatitis could develop ulcers. It is possible that this is the case here. If this is so, the poor blood circulation would need alleviation or correction. Antibiotics such as thyrothricin, together with other appropriate measures, have been found useful for these ulcers. Penicillin also, used locally, probably would be helpful.

GEOGRAPHY OF UPPER RESPIRATORY INFECTIONS

To the Editor:—Will you kindly give me the names of states which show the lowest incidence of upper respiratory infections and sinusitis, also the states which show the highest rates for these two diseases?

R. Thornell Mauer, M.D., Omaha.

ANSWER.—Since the diseases mentioned are not reportable and seldom appear as causes of death, there are no actual statistics on their prevalence in different regions. They seem related more to weather instability (storminess) rather than to any other environmental factor and hence are at a minimum in the Southwest (New Mexico, Arizona and southern California, except along the immediate coastal fringe of 20 miles or so). They are most prevalent in the Missouri, upper Mississippi and Ohio river basins and eastward to the Atlantic coast. Urban atmospheres polluted with domestic flue and industrial wastes greatly intensify the respiratory disease problem.

CHEMISTRY OF DIGESTION

To the Editor:—How many carbon atoms do the breakdown products of carbohydrates, fats and proteins have at the time they are absorbed through the walls of the digestive system? Naturally the compounds at that stage have various molecular sizes. What is the maximum size which can pass into the body in ordinary procedure? M.D., New York.

ANSWER.—Carbohydrates are absorbed from the digestive tract mainly as hexoses, 6 carbon chains; fats are thought to pass into the lymph and then into the blood as resynthesized fats with the intermediate hydrolysis to glycerol and fatty acids, the latter mainly as 16 and 18 carbon chains. Normally the proteins are hydrolyzed in the digestive tract in the main to the amino acid stage and these absorbed into the blood stream. Such amino acids vary in size from 2 carbon to 11 carbon compounds. To some extent peptides, peptones or proteoses may be absorbed, but these forms are not now considered important or high in amounts in the normal absorption of proteins from the digestive tract.

MALARIA IN PREGNANCY

To the Editor:—A woman who is about six months pregnant has malaria. Would it be safe to give quinine sulfate? If so, what dosage? What drugs could be safe for the treatment of malaria in this case?

M.D., New Mexico.

ANSWER.—Although there is considerable doubt whether the therapeutic dose of quinine is sufficient to cause a premature delivery in a six months pregnant subject, a safer drug would be atabrine. The dose of the drug is 0.2 Gm. every six hours for the first day and then 0.1 Gm. three times a day for the five ensuing days.

PIGMENTATION OF SKIN DUE TO SYNTHETIC RUBBER

To the Editor:—A housewife developed a severe dermatitis of her hands following the use of gloves made of synthetic rubber for the purpose of dishwashing. The dermatitis continued despite treatment until the use of the gloves was discontinued. The dermatitis then gradually disappeared but left a pigmentation of the skin around the wrists where the open end of the gloves came in contact with the skin. This pigmentation, apparently in the lowest layer of the skin, is disfiguring and annoying to the patient, as it looks like dirt on the wrists. It has persisted for three months. How can this pigmentation be removed?

W. E. Lowthian, M.D., Baltimore.

ANSWER.—The treatment of hyperpigmentation is notoriously unsuccessful. In time it should disappear. The drug most commonly used for pigment removal is mercury bichloride. The following formula recommended by Von Harlingen may prove of value: mercury bichloride 0.4 Gm., zinc sulfate 2 Gm., lead acetate 2 Gm. and distilled water to make 120 cc.; this should be applied as a lotion morning and evening.

SÄNGER MODIFICATION OF CESAREAN SECTION

To the Editor:—Please describe the Säger modification of cesarean section. M.D., Arizona.

ANSWER.—Säger introduced his modification of the cesarean operation in 1882. De Lee states that the following were the essentials of the operation:

"Median abdominal incision; median uterine incision, with or without eventration of the uterus; use of rubber ligature around cervix to stop hemorrhage; resection of a strip of uterine muscle under the peritoneum; eight or ten interrupted silver wire sero-muscular sutures, avoiding the decidua; twenty to twenty-five interrupted fine silk seroserous (Lembert) sutures; extreme antiseptics."

These safeguards lessened the mortality rate of the operation in those days, but obviously they are not applicable at the present time.

WIRING IN FRACTURES OF THE JAW

To the Editor:—Referring to the answer to the query on "Wiring in Fractures of Jaw" on page 774 of *The Journal*, July 7, 1945, "T. L. Gilmer" should read instead "T. L. Gilmer." Dr. Gilmer began the practice of dentistry in Quincy, Ill., later moving to Chicago, and for years he was connected with the Northwestern University Dental School, where he became famed in the field of oral surgery. The component of the Illinois State Dental Society in which Quincy is located was named "The T. L. Gilmer Component" in his honor. Hugh M. Tarpley, D.D.S., Quincy, Ill.

AMEBIC HEPATITIS

REPORT OF THIRTY-THREE CASES

WILLIAM A. SODEMAN, M.D.

AND

BENTON O. LEWIS, M.D.

NEW ORLEANS

The term amebic hepatitis has been used by some¹ as synonymous with hepatic amebiasis. Most commonly, however, this term is used to indicate the earlier phase of amebic hepatic disease before frank abscess can be diagnosed. Although at times the patient may not complain until frank abscess is present or even until rupture is imminent,² there is much evidence in the literature³ to indicate the importance as a clinical entity of these earlier phases of amebic hepatic disease. Rogers⁴ over thirty years ago described a "presuppurative" stage, by which he meant to differentiate the stage of abscess from simple amebic hepatitis. Actually it is impossible clinically to be certain that small single or multiple abscesses are not present at this time, and diagnosis and treatment at this stage are extremely important. The frequent lack of clarity in discussion of these pictures and the tendency to group amebic hepatitis and amebic hepatic abscess in clinical analyses and statistics have prompted a review of the last 33 cases of amebic hepatitis seen at the New Orleans Charity Hospital and the U. S. Marine Hospital at New Orleans in order to note any differences in the clinical manifestations of these groups and the factors of importance in early diagnosis and, consequently, in early treatment. Certain aspects of some of the cases in the present series have been discussed elsewhere.⁴

CLINICAL PICTURE

All 33 of the patients were adults and 29, or 88 per cent, were men. These findings were to be expected from previous reports. The disease is essentially one of adults, and, in an analysis of hepatic abscess from the records of the Charity Hospital, Ochsner and DeBakey⁵ found 157, or 86.7 per cent, of 181 instances in the male. The same authors, in a review of the literature, found that 95 per cent of 1,789 cases occurred in men.

In the present group the clinical picture showed a number of rather constant characterizing features,

although the complaints on admission at times led to a search for disease in areas outside the liver. Pain in the region of the liver was a universal complaint. It varied from severe and sharp to dull and aching. At times it was constant, at others intermittent. The patient usually complained of pain in the region of the right costal margin, most frequently in the anterior or axillary region but at times posteriorly as well. Fever was present in all but 1. In the more acute pictures it reached 103 to 104 F., was intermittent in type and in 13, or 40 per cent, of the patients was accompanied by chills. Clinical jaundice was present in only 5, or 15.1 per cent, of the patients. Sallowiness of the skin was frequent. Jaundice was therefore not usually present, but its occurrence was sufficiently frequent to bring amebic hepatitis under consideration. Its frequency in amebic hepatitis is variously reported as ranging from 3 to 27 per cent.⁶ Other complaints less regularly present included nausea and vomiting, weakness and loss of weight. In only 9, or 27.3 per cent, of the patients was diarrhea present at the onset or during the course of the hepatic picture. Seven others gave a history of diarrhea, bringing its incidence up to 16 of the 33, or 48.5 per cent. The history of diarrhea may antedate the picture for years but, as shown by the figures just given, was more recent in the majority of the cases.

The most important physical findings were hepatomegaly and tenderness in the region of the liver. Enlargement of the liver was found in 29, or 88 per cent, and tenderness with regularity in 100 per cent. Occasionally tenderness was so severe that the presence or absence of a palpable liver could not be established. The spleen was palpable in 4 patients, 2 of whom gave a history of previous malaria. This finding, therefore, was unusual, but it did not exclude the diagnosis.

The total leukocyte count was elevated in 29, or 88 per cent, averaging 13,000. The incidence of positive stools, roentgenologic findings and data on the complement fixation test are given in the accompanying table and are discussed further on along with the several scattered data on liver function tests.

None of the patients showed the low grade symptomatic picture described by Hurst⁶ and Castellani.⁷ Many had the positive findings described by these authors but had other important findings in addition. The former author described a picture of general unfitness and ease of fatigue with poor appetite, a pale or sallow color, and constant aching and tenderness of the exposed surface of the liver. The levulose test showed evidences of hepatic insufficiency and but rarely were amebic cysts found in the stools. The latter author described a picture interpreted as low grade hepatitis

with evidences of enlargement of the liver to percussion but with the absence of a palpable liver, fever and leukocytosis. In the picture described by Castellani, criteria are not well established, and the proof of its importance has not yet been established by tissue studies. All of our group showed findings without doubt diagnostic of active hepatic disease. The type of onset and the symptoms in our group did vary with the acuteness or chronicity of the process. In 25, or 75.8 per cent, of the patients there was a distinct sudden onset from which the picture could be easily dated. This figure is much higher than some of those given for hepatic amebiasis in other reports,⁵ and in our group of 58 cases of amebic hepatic abscess, including those with pulmonary pictures, only 55 per cent had sudden onset. It is likely, of course, that the more acute pictures would lead to earlier diagnoses, before abscess could be established, and thereby increase the frequency of instances with acute onset in such a group of patients. On occasion the patient may not complain, as already stated, until frank abscess is present or even until rupture is imminent.² It is possible that chronic hepatitis of a very low grade, as just mentioned and as described by Hurst and Castellani, could antedate such instances, but our experience does not add weight to such an assumption. In our 8 patients without dramatic onset,

*Observations in Cases of Amebic Hepatitis and
of Amebic Hepatic Abscess*

	Amebic Hepatitis (33 Cases)	Amebic Hepatic Abscess (58 Cases)
1. A history of diarrhea or dysentery, or its presence with the hepatic picture.....	16 (48.5%)	19 (32.7%)
2. The presence of E. histolytica in the stools	18 (54.5%)	10 (29.4%)
3. Roentgenologic signs	15 (45.4%)	47 (81.0%)
4. Chocolate sauce pus.....	0 (0.0%)	55 (94.8%)
5. Positive complement fixation test.....	1 (50.0%)	2 (100.0%)

that is the chronic group, the clinical findings were essentially of the same type as in the more acute pictures, but of less intensity and less sudden appearance and progress.

DIAGNOSTIC ASPECTS

As with frank abscess, the presenting complaints at times drew attention to areas other than the liver. In abscess with rupture to or through the diaphragm the process is at times mistaken for primary pulmonary disease. In 12, or 20 per cent, of our 58 cases of hepatic abscess, previously reported,⁴ presenting complaints and clinical findings concentrated interest in the right lower pulmonary area with pleural pain, pleural effusion and evidence of pneumonitis as outstanding pictures. All showed, in addition to the pulmonary findings, evidences of hepatic involvement. In the remaining 46 patients the complaints on admission pointed definitely to the abdomen and specifically to the liver. In the present group obviously without spread of the disease to the pulmonary area, the complaints occasionally led to the consideration of a pulmonary diagnosis. This was true in 3 instances (9.1 per cent), and in all 3 the suspicion of pulmonary disease was based entirely on the type of pain. One patient had pain referred to the right shoulder accentuated by breathing; the other 2 knifelike pain along the right costal margin near the midaxillary line, which again led to a consideration of pleurisy as a diagnosis. All in all, in amebic hepatitis pulmonary pictures do not attain the importance they do in certain instances of abscess, and

in our group the consideration of pulmonary pictures rested entirely on first impressions of the possible source of pain. Under such circumstances suggestive evidence of pulmonary involvement may be found in the chest roentgenogram, for, with involvement of the diaphragm immobilization of the right base may at times cause some increased densities in the lower right pulmonary area which have been mistakenly interpreted as pneumonitis.

The clinical pictures were similar to those seen in some days or weeks in developing hepatic abscess. Indeed it is the same process. In the group of patients with amebic hepatitis, as in those diagnosed as amebic hepatic abscess, a number of admission diagnoses other than amebic disease were made. These included cirrhosis and cancer of the liver, acute and chronic cholecystitis, peptic ulcer, infectious hepatitis, pyogenic liver abscess, carcinoma of the colon, pyelonephritis and pleuritis, the diagnosis varying with the onset, severity and type of picture. In 1 instance there was at the onset a lack of localizing signs in the liver area, so that the differential diagnosis involved the consideration of febrile disease without localizing signs; for example, brucellosis and malaria. Those conditions which at times fall into a group called "fever of undetermined origin" are therefore considered in differential diagnosis. This list of diagnoses does not represent all the conditions with which amebic hepatitis may be confused. It does represent those which came under consideration in our patients before the true diagnosis was made.

The most important fact which our series shows is the need for consideration in diagnosis of the possibility of the occurrence of hepatic amebiasis. In the hospital with which we are associated some of the conditions that have been listed are many times more common than hepatic amebiasis. The same is true in many, if not all, communities in this country, and the possibility of the occurrence of amebic hepatic disease does not always come to mind. In some tropical areas in which hepatic amebiasis is more common in relationship to these other pictures, the possibility of its presence is uppermost in the mind of the examiner. This is not true, in general, in our community, and the condition does not always come to mind. This our records show very clearly. Awareness of the possible occurrence of hepatic amebiasis was therefore the most important single factor in the early establishment of the diagnosis. Without it, diagnoses were either late or accidental. Most important is the fact that geography cannot be used to rule out the possibility, for amebiasis is found wherever it is sought.

As already stated, the clinical findings described as making up the symptom complex of amebic hepatitis included leukocytosis in 88 per cent of our patients. This is an extremely important finding, although the white blood count may vary into the range of normal from time to time in the same patient. The average count in our patients was 13,000, the highest being 26,000 and the lowest 6,200. In general the counts were higher in the more acute pictures. With abscess Ochsner and DeBakey² found an average of 16,450, and in pyogenic abscess of the liver 26,924. Eosinophilia was not in evidence. The percentage of neutrophils averaged 74. While the absence of leukocytosis is a point against the possible diagnosis of amebic hepatitis, repetition of the white blood count is indicated because of its variability, and search for collateral diagnostic data for amebiasis is still indicated because of the occurrence of normal counts in 12 per cent or more of the cases.

ACC-444

The occurrence of jaundice in 15 per cent of our patients produced a clinical entity which simulated certain other types of hepatitis generally considered in the differential diagnosis of so-called catarrhal jaundice and acute infectious hepatitis. Here the presence of leukocytosis and the collateral diagnostic data for amebiasis which we have already mentioned are extremely important. Several of the other types of specific hepatitis may also give leukocytosis. Within a period of three days one of us recently saw 3 patients with fever, jaundice and enlargement and tenderness of the liver and elevated white blood counts. Each of these patients showed one of the specific types of hepatitis seen in our community, amebic hepatitis, Weil's disease and infectious mononucleosis. Palpability or lack of palpability of the spleen was not helpful in differential diagnosis. With amebic hepatitis and jaundice our patients have shown icterus indexes as high as 70, positive urobilinogen tests, mild reductions in serum proteins in 2 patients, indirect positive van den Bergh tests in 3 and impaired hippuric acid secretion and galactose tolerance tests in 1 patient each. The cephalin flocculation test was positive in the 1 case in which it was done. Bile was present in the stools in all 5 patients with jaundice. Obviously our data on liver function tests in these patients are inadequate and fragmentary. More adequate investigations from this standpoint are necessary to make these tests of value in diagnosis.

Demonstration of the etiologic agent in any disease places therapy on solid ground. Amebiasis is no exception and the study of the stools in suspected colonic involvement, especially with a check of at least three stools followed by a purge specimen, is said to have an efficiency in diagnosis of about 90 per cent.⁸ However, in hepatic involvement, diagnosis and treatment are almost invariably carried out without demonstration of *Endameba histolytica* in the liver or its discharges. The organism cannot be demonstrated in the involved structures until pus is obtained, and even then it is found with difficulty. The gross appearance of the pus is so characteristic that, for practical purposes, it is diagnostic, although occasionally pus of this appearance is not amebic, and amebic pus occasionally is light creamy in appearance. In our group of 58 cases previously reported, the diagnosis was finally settled in this way in 55. However, pus was demonstrated early in the observation of the patient in only 27 of the 55 instances, which indicates the delay in diagnosis and treatment entailed by temporizing for this final criterion. If the diagnosis is suspected from the clinical pictures already described, certain data may be actively sought before pus is demonstrated to arouse the clinical suspicion of the disease to a level sufficiently high to warrant treatment. These findings and the frequency of their occurrence in the present group of patients, as well as in the group previously reported with abscess, are shown in the table. It will be seen that not one of the collateral items is in itself diagnostic of hepatic amebiasis, but since the diagnosis of this disease approaches desirable criteria, only when characteristic pus is obtained, and since this is late in the disease, we must depend on findings less diagnostic than the ideal or sit back and wait until the disease has progressed to its advanced stages. In 50 of the cases diagnosed as abscess, the onset of the picture was established with

some certainty and varied from two weeks to five months, with an average of six and a half weeks from onset until the diagnosis was satisfactorily established. This time interval indicates that a search for the collateral data given in the table may lead to a presumptive diagnosis of amebic hepatic disease in the absence of the demonstration of other causes for the clinical picture and will warrant active therapy with emetine before pus is obtained.

The differentiation of patients into two groups, one with simple amebic hepatitis and the other with amebic hepatic abscess, is a purely clinical division and from the standpoint of treatment is extremely important. By no means short of autopsy can one clearly establish a diagnosis of hepatitis without abscess. Although Rogers described a presuppurative stage, it is impossible to be certain that small single or multiple abscesses are not present without location or size which cause bulging. Amebic hepatitis is the earlier stage of the disease and, even when some liquefaction has taken place in the hepatic lesions, closed drainage is not essential to cure. Emetine alone⁹ is known to be successful at times, even when pus is present. Even large abscesses may at times disappear with emetine therapy alone, but in most such cases evacuation of pus is necessary and should not be delayed if danger of rupture is imminent. Two to four days of emetine therapy should be carried out before aspiration when possible, and will, in effect, eliminate the necessity for aspiration at times, as well as reduce the complications attendant on aspiration if it is found necessary. The presence of secondary bacterial infection in abscess cavities has demanded resort to open rather than closed drainage, a procedure which is accompanied by a sharp increase in mortality. Recently the use of sulfonamides¹⁰ and penicillin¹¹ has been shown to permit closed drainage when organisms sensitive to these agents have been the contaminants.

Berne's remarks¹² on the process going on in the liver are important. He emphasized that it represents a special type of liver necrosis, as is a gumma, and that emetine is approximately as specific as is neoarsphenamine. He further emphasized that, if it was looked on as being similar to a broken down gumma with aseptic evacuation of its contents often required to eliminate a foreign body factor, the proper orientation for treatment would be established. Dangers of rupture and spread of the process with additional mortality from these complications demand closed drainage, preferably preceded by emetine when pus is located.

Since the diagnosis is a matter of estimation of the stage of the process, one should not expect a remarkable difference between the two in factors 1, 2 and 5 in the table. The differences rest most probably on at least two bases, first variations in the diligence of examiners in the various hospital services and secondly on the small size of the groups, which renders comparative figures difficult to interpret. Colonic infection probably always precedes the hepatic lesion but in many instances is not clinically active. Right sided colonic disease particularly may give little in the way of symptoms or signs. In only 32 per cent of those diagnosed as having abscess and in 48.5 per cent of those diag-

nosed as having amebic hepatitis, a history of diarrhea was obtained. These figures vary considerably in reported groups of hepatic amebiasis in the literature. In some groups the history of diarrhea has occurred in as high as 90 per cent of the patients.¹³ This finding became more important clinically when it was recent and the characteristics were clear in the patient's mind. Certainly with a story having the characteristics of amebic dysentery in the presence of the hepatic picture as described when the considerations in differential diagnosis already given are exhausted, a therapeutic trial with emetine is indicated. It must be noted that absence of diarrhea is sufficiently frequent that the lack of a positive history is not helpful in exclusion of the diagnosis. Again, the establishment of the diarrhea as a manifestation of amebiasis or the finding of positive stools without a diarrhea was extremely important, for it established in the patient the presence of the etiologic agent. *E. histolytica* has been reported as present in from 4 to 70 per cent of patients with amebic hepatic disease.¹⁴ In our group examinations were not always adequate, so that the figures should be higher than those stated. In New Orleans, where over 10 per cent of the clinic population has cysts of *E. histolytica* in the stools,¹⁵ obviously in approximately that percentage of patients with any disease—whether cirrhosis of the liver, peptic ulcer or any other disturbance—stools would be likely to be positive. This finding, therefore, is not pathognomonic of hepatic amebiasis, but under any circumstances it establishes the presence of the causative agent in the body of the patient, and in the presence of the hepatic pictures we have described, without any other adequate explanation for that picture, a course of emetine is indicated.

In our hands this has consisted of six to ten daily injections, preferably intramuscularly, of 1 grain (0.06 Gm.) of emetine hydrochloride followed by a full course of iodoquin (three tablets of 3.2 grains [0.2 Gm.] each three times daily for five days) whether or not *E. histolytica* has been demonstrated in the stools, for the colon is the assumed source. Prolonged use of emetine may lead to cardiac damage. Arrhythmia and congestive heart failure are the chief findings, and diarrhea, nausea, vomiting, prostration, muscular pains and weakness may develop. In our patients restriction of the dose to that just stated has resulted in untoward results in only 1 of 91 patients.

One cannot overemphasize in amebic hepatitis the importance of the roentgenographic examination, especially fluoroscopic study for impaired or paradoxical motion as well as elevation of the diaphragm. Recently emphasis has been placed on lesser degrees of restricted movement of the diaphragm, which may be the only sign of liver involvement.¹ Munk has emphasized Müller's test (positive with upward movement of the diaphragm on inspiration against a closed glottis) and Hitzenger's test (the same action with "sniffing"). Both of these tests may be positive in phrenic paralysis, eventration of the diaphragm or local damage to the diaphragmatic muscle. Pleurisy from any cause may impair diaphragmatic movement, and elevation of the diaphragm occurs from all types of increased intra-abdominal pressure as well as from infectious hepatitis and other types of hepatomegaly. Some types of pulmonary disease, bronchostenosis, for example, may give

paradoxical movement of the diaphragm. Also in amebic hepatitis or amebic hepatic abscess the diaphragm may show no change if the upper portion of the liver is not remarkably involved.

In the present group roentgenologic signs were absent in 18 of the 33 patients, or 54.6 per cent. With the development of abscess roentgenologic findings were twice as frequent, with evidence of bulging or of extension of the disease in 56.9 per cent of the patients and positive roentgenologic findings in 81 per cent. Evidences of bulging or extension of the disease were absent in the patients with hepatitis, where elevation and impaired movement of the diaphragm were the only findings. The latter finding alone occurred in 18, or 31 per cent, of our patients with abscess, a figure more in keeping with the 45.4 per cent in hepatitis. Thus, roentgenologic findings become more positive in the more advanced pictures, finally acting as an important guide for the aspiration of pus. We need not mention other evidences of abscess formation, for we are not concerned with these advanced pictures here. They have been ably discussed by Ochsner and DeBakey.⁵

In the patients diagnosed as having amebic hepatitis, pus was, of course, not demonstrated. Chocolate-sauce appearance is the closest approach to a final diagnostic criterion, and its absence makes the other collateral data extremely important in the establishment of a diagnosis. The occurrence in combination in the same patient of several of these findings makes the presumptive diagnosis one of high degree. Twelve of the patients showed the findings 1 with 2, 3 or both in the table. Seven showed 1 or 2 without 3. In only 2 was 5, the complement fixation test of Craig, done. One was positive, the other anticomplementary. This is the most glaring inadequacy in our data. Certainly awareness of the possible occurrence of amebic hepatitis from the clinical picture together with the positive complement fixation test would give the earliest possible combination for a presumptive diagnosis which would lead to early therapy. Such an approach would reduce the number of patients reaching the stage in which pus is demonstrable. In our abscess group the mortality rate was 5.2 per cent; in the group with hepatitis, 0 per cent. Hence the need for further development and more widespread use of the complement fixation test is evident. There are certain technical problems at present which interfere with the widespread use of, and the reliability of, this test.¹⁶ At present we must send material away for the complement fixation test, and the problem in diagnosis has usually been settled by the time the results are obtained. Collateral diagnostic data were helpful in 24 of the 33 patients. In 9 the diagnosis was unsupported by collateral findings. Here the complement fixation test would have been particularly helpful.

Many times then, as we have stated previously,⁴ the clinician standing at the bedside of the patient should and must make a diagnosis in the presence of the clinical picture but in the absence of absolute data, despite the fact that he is extremely anxious for such information and may have sought it diligently. If he elects to withhold specific treatment because of the inadequacy of diagnostic findings, the picture will either progress to resolution as a natural course of events or progress until definite evidence, either by bulging or by rupture.

indicates the presence of hepatic abscess. His alternative is to elect to treat the patient with emetine because of the high clinical suspicion of the disease and to determine through therapeutic results the presence of amebic hepatitis or, with high probability, the absence of this disease if therapy is not effective. In our opinion the latter course is the more desirable for, as we have said, in our groups the comparative mortality has been 5.2 and 0 per cent respectively. This situation is by no means peculiar to hepatic amebiasis. In pulmonary tuberculosis the diagnosis rests on the demonstration of the tubercle bacillus in the sputum or in the tissues. The clinician's greatest desire, however, is to diagnose and treat the disease sufficiently early so that it is impossible to demonstrate clinically the presence of the tubercle bacillus. This desire should also apply to amebic hepatic disease. In any disease in which results in therapy are based primarily on early diagnosis, the absolute criteria for diagnosis are likely to be absent. Errors in diagnosis are likely to occur, but if one waits until criteria are absolutely fulfilled great hazard is added to the life of the patient and potential benefits from treatment are greatly reduced. No better examples of these principles can be found than in the early treatment of tuberculosis, carcinoma and amebic hepatic disease.

The history and physical examination uncovering the hepatic clinical picture already described do not warrant a therapeutic test until other possibilities in diagnosis are considered and evidence speaks against them, while the awareness of the possible occurrence of amebic infection is leading to efforts to establish the presence of colonic amebiasis, roentgenologic findings in the liver area, a positive complement fixation test or, finally, pus, if a desirable area for tap is found. The promiscuous use of emetine, without the aforementioned attempts, is to be discouraged.

If treatment with emetine is rewarded by cure, two possibilities exist. Either the therapy and cure were coincidental, or there was a cause and effect relationship. The former is possible if the diagnosis has been in error. The latter is also possible with errors in diagnosis. Emetine is credited with striking therapeutic effects in other diseases involving the liver,

Chart 1.—Temperature of a patient in the present series, showing characteristic response to emetine therapy.

including schistosomiasis, fascioliasis and paragonimiasis.¹⁷ These possibilities are brought out in the temperature charts. Chart 1 gives the temperature of a patient in the present group who showed the clinical evidence we have described in the presence of positive roentgenologic findings and *E. histolytica* cysts in the stools. The effect of emetine therapy, as indicated in the chart, was the clearing of the entire picture

and the return of the temperature to normal. A period of one week is omitted from the chart, as indicated, in order to conserve space. Follow-up on this patient indicated that there was no return of the picture over a period of eighteen months. Chart 2 is that of a patient who had a comparable picture with tenderness and enlargement of the liver but without positive roentgenologic findings and without colonic amebiasis and

Chart 2.—Temperature of a patient not in the present series but with a similar clinical picture and no confirmatory collateral findings. The arrow indicates the time at which emetine might have been given and cure assumed from the response.

in whom the diagnosis was therefore in doubt. The arrow indicates the time at which emetine probably would have been given if the diagnosis had been strongly suspected from the collateral findings. However, the patient was not treated and the resolution of the fever, as shown in the chart, was spontaneous. The clinical picture also cleared and over a period of fifteen months repeated examinations of the stools for *E. histolytica* were negative and there was no recurrence of the symptoms or signs which prompted the admission to the hospital. Because of inadequate criteria for diagnosis, an occasional self-limited disease of the liver may be treated as amebiasis. Brookfield¹⁷ has recently reported such a case with spontaneous recovery.

While spontaneous cure or a remission in hepatic amebiasis is possible, the added risk attending the progress of the picture to a definite stage of abscess is so great that no one should permit it merely to satisfy his diagnostic curiosity. The introduction of closed drainage with emetine reduced the mortality from amebic hepatic abscess from figures over 50 per cent to 5 to 14 per cent.⁵ Awareness of the possibility of the occurrence of this disease, when the clinical findings occur, plus early treatment with adequate doses of emetine alone should make this figure approach zero.

CONCLUSIONS

1. The most important factor in the early recognition of amebic hepatitis is the awareness of the possible occurrence of the disease.

2. The presence of jaundice in about 15 per cent of the patients with amebic hepatitis in this series indicates the necessity for consideration of amebiasis as a cause of hepatitis with jaundice along with Weil's disease, infectious mononucleosis and other specific types of hepatitis when this picture presents itself. Evidences of impaired liver function by various liver function tests may be present. Our data on these points are fragmentary, and more investigations of this type on such patients are indicated.

3. Early diagnosis of hepatic amebiasis was shown in our group of patients to rest on collateral diagnostic findings, especially the presence of intestinal amebiasis, roentgenologic signs and the complement fixation test. More widespread use of the latter test is indicated.

17. Brookfield, R. W.: Acute Hepatitis Without Jaundice in West Africa, *Tr. Roy. Soc. Trop. Med. & Hyg.* 38: 25, 1944.

4. Early diagnosis, before the stage in which pus could be demonstrated, in our group, led to effective treatment with emetine alone. Dangerous procedures and the stage of the disease in which prognosis is at its worst were thereby avoided, with pronounced reduction in the mortality rate.

5. Diagnoses based on the criterion of characteristic pus will always be late, and our chances of an early preventive and therapeutic approach will be small.

6. Diligence and care in the demonstration of evidences of amebiasis in patients with such clinical pictures, through stool and roentgenologic examinations, and the complement fixation test, together with clinical acumen in ruling out other causes of the clinical picture, should reduce both errors in diagnosis and promiscuous use of emetine to a minimum, and, despite occasional errors in diagnosis, will place the treatment of hepatic amebiasis on the desirable plane on which the treatment of early carcinoma and early pulmonary tuberculosis now rests.

CRITERIA IN THE MANAGEMENT OF CHRONIC ILEITIS

EVERETT D. KIEFER, M.D.

AND

JOHN R. ROSS, M.D.

BOSTON

Before regional ileitis was established as a disease entity by Crohn and his co-workers¹ in 1932, this condition was thought to be a form of tuberculous enteritis. In many instances the existence of a small intestinal lesion was not even recognized, owing to a well known lag in the development of both clinical and roentgenologic diagnosis of disease of the small intestine.

DIAGNOSIS

Our first diagnoses of regional ileitis were made in flagrant cases of this condition with extensive and chronic lesions. As we have learned more concerning the clinical course and the corresponding pathologic changes that occur in the wall of the small bowel, the diagnosis has been made in the earlier stages and in instances of less extensive disease.

In any attempt to set up minimal criteria for the diagnosis of regional ileitis, the acute forms must be considered separately from the chronic stage.

The onset of ileitis may be gradual and insidious, with grumbling right lower quadrant symptoms and mild diarrhea, which in a few weeks may become severe enough to lead to either roentgenologic study or a laparotomy. There is also an acute onset characterized by abdominal pain localizing in the right lower quadrant with vomiting and diarrhea. Fever, leukocytosis, tenderness and muscle spasm may complete a clinical picture that is indistinguishable from acute appendicitis, with a result that many diagnoses of acute ileitis are made at the operating table.

Acute Ileitis.—In the present study of 107 cases of ileitis, 11 patients had the disease in the early acute stage. This was proved in every case by laparotomy, at which the surgeon reported inflamed, edematous and

thickened loops of small intestine and acute lymphadenitis in the mesenteric nodes.

This is not an accurate indication of the relative incidence of the acute and chronic stages of ileitis, since this material was taken from a gastroenterologic and surgical service organized chiefly for the treatment of chronic disease. Relatively few abdominal emergencies are admitted.

Of the 11 cases diagnosed early acute ileitis at operation, 7 had roentgenologic examination just before the operation and 1 within a few days after the abdomen was explored. Of these 7 cases, 5 showed variations from the normal appearance of the small intestine.

These cases, although few in number, constitute an important group because they supply clinical and roentgenologic data on proved cases of ileitis in its earliest stages when organic pathologic changes are minimal.

Figure 1 is a roentgenogram of a patient with early ileitis who had had abdominal pain and mild diarrhea for several weeks and an acute flare-up of right lower quadrant pain and tenderness, fever and a leukocytosis of 14,000. An operation for suspected acute appendicitis disclosed typical acute terminal ileitis. This roentgenogram was made fourteen days after the laparotomy and demonstrates the minimal changes in the terminal ileum which can be considered diagnostic. Only when these changes are relatively constant in a series of roentgenograms are they really convincing. In an analysis of the evidence of disease shown in this roentgenogram, the following features may be listed:

1. Some hypermotility in the small bowel.
2. Somewhat widely separated loops of terminal ileum suggesting thickening of the intestinal wall and mesentery.
3. Unusually long segments of pronounced spasm.
4. Irregularities of the mucosal pattern suggesting edema of the mucosa with flattening and rearrangement of the folds.

These roentgenologic details should prevent confusion with such findings as shown in figure 2. This roentgenogram shows definite segmentation of the barium in the ileum. These segments are more or less uniform in size, while serial roentgenograms show no constancy in their shape. The string sign is absent. These findings, which may be produced by any acute irritation of the small intestine, are frequently seen after catharsis. This patient was operated on two days later and found to have no organic disease of the small intestine.

Chronic Ileitis.—Our study of the diagnostic problems presented by regional ileitis in its chronic ulcerative and cicatrizing stages also was limited to cases in which the diagnosis was proved by laparotomy.

A review of the symptoms in 107 cases revealed the following incidence of important symptoms: pain, 92 cases; malnutrition with weight loss, 80 cases; fever, 65 cases; diarrhea, 60 cases; external fistula, 23 cases; abdominal mass, 40 cases, and anemia, 42 cases. The most important symptom in directing attention to the intestinal tract was pain; diarrhea was next.

A complete diagnosis in cases of chronic enteritis includes a determination of the location and extent of the disease, as well as its complications, which involve intestinal obstruction and perforations resulting in internal or external fistulas or abscesses. This information usually can be obtained by roentgenologic studies of the small intestine by barium meal and by the injection of external fistulas with iodized oil. These signs frequently are extensive and easily recognized, but from the standpoint of broadening the range of roentgenologic diagnosis the proved cases with minimal findings are of special interest.

From the Department of Gastro-Enterology, the Lahey Clinic.
Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1. Crohn, B. B.; Ginzburg, L., and Oppenheimer, G.: Regional Ileitis: A Pathologic and Clinical Entity, *J. A. M. A.* 99: 1323-1329 (Oct. 15) 1932.

Figure 3 is a roentgenogram of a patient who presented only mild and unimpressive symptoms which consisted of bouts of mild abdominal pain. The findings here are certainly minimal, and if the stringlike appearance of the terminal ileum had not been constant in other roentgenograms it might easily have been

Fig 1—Five hours after a barium meal: hypermotility in the small bowel, separation of the loops of the terminal ileum, long segments of pronounced spasm and irregularities of the mucosal pattern. Diagnosis, early acute ileitis

considered nondiagnostic. However, at laparotomy there was a definite nonobstructing ileitis involving the terminal 12 inches of small intestine, which demonstrates the diagnostic importance of even slight variations from the normal pattern, provided the distortions are constant in serial roentgenograms.

When partial or complete obstruction of the small intestine develops as a complication of regional ileitis, the abdominal symptoms become more severe and the roentgenologic signs of disease are more striking. Stasis and dilatation of the small bowel are the outstanding features and may be quite pronounced without demonstrating any special characteristics that identify the nature of the obstructing lesion. For example, figure 4 shows considerable obstruction and dilatation of the ileal loops but no changes in the small intestine that are characteristic of chronic inflammation. The diagnosis of ileitis in such a case depends on the clinical features and often cannot be definite.

If, on the other hand, dilated loops of the small intestine are accompanied by distal areas of characteristic narrowing and rigidity (fig. 5), the diagnosis of chronic cicatrizing enteritis with obstruction is quite certain.

Another complication which influences the clinical picture, prognosis and plans for treatment is chronic perforation with external and internal fistulas and abscess formation. This complication usually produces striking roentgenologic effects which may be either confusing or enlightening.

Fistula formation is so characteristic of chronic ileitis that the finding of an internal or external tract connecting with the small intestine is strong presumptive evidence of ileitis. If, in addition, there are loops of small bowel showing the typical changes of chronic inflammatory disease, the diagnosis is on a sound basis. In figure 6 the ileum shows extensive typical deformity with multiple internal fistulas between the diseased portion of the small intestine and the colon. This patient also had external fistulas.

TREATMENT

The management of chronic ulcerative enteritis depends on the following factors:

1. Stage of morbid process
2. Location and extent of involvement in the small intestine
3. Activity of the inflammatory, ulcerative and cicatrizing process
4. Complications.

This disease has a profound tendency to run a chronic, slowly progressive course for an indefinite period. Although clinical remissions are fairly common, and in certain instances the morbid process appears to be permanently arrested, most cases tend to follow a relentless course with symptoms due to the persistent hyperplastic intestinal lesions and the formation of obstructive granulomas and perforations into adjacent regions.

Fig 2—Four hours after a barium meal: segmentation of barium in uniform sized masses, no rigidity or constancy in shape, and no string sign. Diagnosis, no organic disease; irritation of the ileum.

Experience in the treatment of chronic regional enteritis has proved that in properly selected cases surgical measures are successful and satisfactory. Marshall² has described the surgical measures employed in this series and has reported the clinical results.

2. Marshall, S. F.: Regional Ileitis. Surgical Management and Results of Operation, *S. Clin. North America* 23: 873-880 (June) 1943.

The selection of the type of management for cases of regional ileitis may be somewhat simplified by the classification of cases into clinical groups, as follows:

1. Early acute enteritis without complications.
2. Chronic terminal ileitis without complications.
3. Chronic terminal ileitis with complications (obstruction or perforation)
4. Extensive segmental ileojejunitis without complications
5. Extensive segmental ileojejunitis with complications

In an effort to formulate a policy in the management of this condition, our cases were separated according to this classification, and the clinical results of the various forms of therapy tabulated for each group.

1. Eleven Cases of Early Acute Enteritis Without Complications.—No patient in this group was treated surgically except for abdominal exploration with or without appendectomy. There was one hospital death two weeks after admission due to fulminating terminal ileitis with multiple perforations and peritonitis. Another patient died three months after exploration, but the cause of death is unknown. Of the remaining 9 patients, 4 have been well for over a year, and recent roentgenograms in 3 show little or no variations from normal. Four patients have had a recurrence of the disease and have required surgical resection of the ileocecal region with ileocolostomy. A fifth patient has roentgenologic evidence of progressive ileitis, but this has not been proved by operation.

Fig. 3—Five hours after a barium meal hypermotility of small intestine and a contracted stringlike terminal ileum which was also present in other films. Diagnosis, terminal ileitis

Conclusions.—In this group operative treatment is best deferred, since approximately two fifths of the cases clear up satisfactorily without surgery. Also the limits of the disease become more clearly defined in the more chronic stage, which aids in deciding on the extent of the surgical resection.

2. Eighteen Cases of Chronic Terminal Ileitis Without Complications.—Four of these 18 patients had recur-

rent terminal ileitis after an operation performed elsewhere. Eight patients were treated by a medical regimen,³ with satisfactory results in 4 cases. In 1 case no follow-up information is available. Three patients had persistent symptoms, which required subsequent surgical resection in 2.

Fig. 4—Six hours after a barium meal stasis in a much dilated ileum. The nature of the obstruction is not clearly shown. Diagnosis, chronic ileac obstruction, possibly terminal ileitis

A total of 12 patients were operated on, resection of the diseased portion of the ileum and proximal colon with ileocolostomy being done. There were no deaths. In 11 cases the results are satisfactory, with follow-up data covering a period of from six months to five years. One patient has roentgenologic and clinical evidence of recurrent ileitis proximal to the ileocolostomy, but this has not been proved by laparotomy.

Conclusions.—In cases in which the disease is relatively mild, a medical regimen should be given a trial with the hope that a prolonged remission will result or the morbid process will become arrested before serious damage is done. Probably in not more than half of the cases treated in this way will the results be satisfactory. In a majority of these cases surgery is necessary, and, as far as can be concluded from a small group, resection of the diseased ileum and the ascending colon is a safe procedure and yields satisfactory results in a large proportion of cases.

3. Fifty-Six Cases of Chronic Terminal Ileitis With Complications.—In 31 of the 56 cases in this group, the complication was obstruction, and in 27 it was perforation, with or without obstruction. Fourteen

³ There is no specific medical treatment for regional ileitis. The medical management referred to consists mainly in general supportive measures, which include bed rest for varied periods of time, usually several weeks. The diets used were bland and low in roughage, without cold foods or drinks. The protein content of the diet was maintained at a high level. Supplemental vitamins were used in moderate doses over long periods of time. Ferric sulfate was used for anemia. Transfusions were given when the hemoglobin or plasma proteins were low. The sulfonamides were tried in a few cases without any definite evidence of benefit.

patients were tried on a medical regimen, with the addition of simple drainage of an abscess in 1 case. Of these, no follow-up information is available in 2 cases. Three patients obtained satisfactory results. Nine patients later came to operation for resection of the ileum and right colon (8 performed in the clinic and 1 elsewhere).

Six patients had an ileocolostomy without resection of any intestine. In 2 of these the results were good; there was one postoperative death due to sepsis. Three patients later required resection (2 performed in the clinic and 1 elsewhere).

There were 44 resections of the ileum and right colon, including 2 cases in which an ileocolostomy was performed first. There was one postoperative death due to embolism. There were 8 recurrences after resection, proved by operation in 7 and by subsequent death from sepsis in the eighth. One other patient had clinical and roentgenologic evidence of recurrence, which was not confirmed by laparotomy. In 35 of the 44 cases of resection the results were satisfactory. In all but 7, follow-up data covered a period of over one year.

Ileostomy was performed on 2 patients, 1 of whom died postoperatively of sepsis; the other is well.

Conclusions.—1. Medical management alone has little to offer patients with chronic terminal ileitis with either complicating obstruction or perforation.

2. Ileocolostomy without resection is unsatisfactory in complicated cases, except as a preliminary step to resection.

3. The operative mortality of ileo-ascending colectomy is remarkably low in the hands of an experienced surgeon.

Fig 5—Six hours after a barium meal: delay and dilatation of the ileum above an area that is rigidly contracted and irregular in outline. Diagnosis, chronic terminal ileitis with obstruction.

4. There is a fairly high rate of recurrence of the disease even after removal of all involved areas.

4. **Eight Cases of Segmental Ileocejunitis Without Complications.**—Seven of these 8 cases were treated with a medical regimen. Although exploration was done in 3 there was no surgical treatment. Of the 7

patients, 1 is dead of malnutrition, 1 has not improved satisfactorily, 4 are improved and 1 was not followed.

The 1 patient treated surgically with resection of a large portion of the small intestine developed recurrent enteritis and died.

Fig 6—Four hours after a barium meal: extensive involvement of the ileum with narrowing, loss of flexibility and irregularities of mucosal pattern combined with multiple fistulous tracts between the ileum and the colon. Diagnosis, chronic terminal ileitis with internal fistula.

Comment.—Surgical treatment in cases of segmental enteritis presents a more difficult problem, particularly when the enteritis is widespread and involves so much of the small intestine that it cannot be eradicated completely without jeopardizing the absorptive function. Experience has shown that, if all inflamed loops of small bowel are not removed, recurrence or inadequate control of the disease is the result. Medical treatment can scarcely be expected to effect a cure, but most patients can be improved and in some instances the active disease appears to become arrested. Altogether the management of extensive segmental enteritis is less satisfactory than the treatment of localized terminal ileitis.

5. **Nine Cases of Segmental Ileocejunitis With Complications.**—In 7 of these 9 cases the complication was obstruction, and in 2 it was chronic perforation with abscess. Two patients were treated for a trial period on a medical regimen, but both came to operation. Including those patients who were operated on without trial medical treatment, 9 were treated surgically. Included in the surgical cases are 6 in whom resection of the diseased area was performed with end to end anastomosis. The clinical results were satisfactory in 5 cases, with follow-up for more than a year in all but 1. The sixth patient is improved but shows clinical and roentgenologic evidence of recurrence of enter-

itis which has not been confirmed by operation. In 3 cases the surgical measures consisted of enterenterostomy without resection, with clinically satisfactory results. There were no postoperative deaths in groups 4 and 5.

When complications are present, surgery offers the only possible solution. In some cases all disease can be resected; in others, enterenterostomy may lead to satisfactory relief. Since preoperative determination of the extent of involvement is impossible, exploratory laparotomy is probably justified in a majority of cases.

COMMENT

On the basis of the experience reported here with the treatment of 102 cases of chronic ulcerative enteritis, conservative management is indicated in the early acute forms of the disease, in mild cases of chronic uncomplicating terminal ileitis and in uncomplicated segmental enteritis with extensive involvement of the jejunum and ileum.

As a general rule, chronic terminal ileitis is best treated surgically. This is in agreement with the conclusions of Ginzburg and Garlock.⁴ When the enteritis is complicated by obstruction, fistulas or abscesses, surgical measures are definitely the treatment of choice.

Although surgery is not successful in all cases, the resection of the inflamed loops of intestine produces a high percentage of satisfactory results. Another point favoring surgical measures is the low operative mortality.

ABSTRACT OF DISCUSSION

DR. J. ARNOLD BARGEN, Rochester, Minn.: This disease still offers a challenge to every physician who is unfortunate enough to have to deal with patients so afflicted, since the cause is as yet unknown, the origin of the infection remains obscure and the course of the disease, once well established, is relentless in its advance and destructive nature. Moreover, it is not at all established that we are dealing with a single disease entity. The greatest service that Drs. Kiefer and Ross's discussion has accomplished is their classification of these conditions into the various groups, from an "early acute enteritis" to "extensive segmental enteritis with complications." By so doing they have advanced our ability to study, if not actually our knowledge of this problem materially. I am not convinced that these cases are all a part of one entity. It is more logical to consider these different forms as separate entities, although I can present no clear evidence for this suggestion. It is rather an impression I have gained through a fairly large experience in the handling of similar cases. The course of the cases of extensive "segmental ileojejunitis" varies considerably from that of the typical cases of cicatrizing "terminal ileitis." Any one who has seen a considerable number of the various groups of these patients must have been confronted with the question of explaining their variable course on the basis of single or multiple entities. More recently some observers have separated some cases of sarcoidosis from groups of cases formerly laboring under the designation of regional enteritis. Localized Hodgkin's disease has occasionally been mistaken for regional enteritis. Until the question of multiple entities can be more clearly defined, we shall do well to follow the practical classification which has been offered to us. It at once separates the cases for a reasonable therapeutic approach. It is of the utmost importance to decide as early in the course of the disease as possible whether medical measures are to be employed or whether surgical resection should be undertaken. We have administered the various sulfonamide drugs, i. e. succinylsulfathiazole, sulfaguanidine and sulfathalidine, to these patients, together with other supportive measures, and the response to such a program has in some instances determined the advisability or need of surgery. I

wonder if Dr. Kiefer would elaborate further on the nature of his medical regimen? I have been more successful in making the diagnosis of the lesions of the terminal ileum by retrograde barium injection instead of the barium meal studies; moreover, in the obstructive cases the risk associated with the passage of the column of barium from above is eliminated. I know that a technic suitable in the hands of one is not always the most satisfactory in the hands of others.

DR. HENRY A. RAFSKY, New York: I should like to ask Dr. Kiefer what the age incidence was in his cases. My experience has been that the younger the patients the more refractory they are to either medical or surgical treatment. In the management of these cases more attention should be paid to upper respiratory diseases, especially infections of the throat, as factors in producing acute exacerbations. A girl aged 16 years was first observed in August 1942. She developed ileitis after a streptococcal infection of the throat. She responded to medical measures and was well until November 1942, when she had a recurrence of the ileitis. She was operated on at the Lenox Hill Hospital. An ileotransverse colostomy with an exclusion of the diseased loop was performed. The patient was well until May 1943, when she had a recurrence. Her symptoms steadily increased and in November 1943 she was again admitted to the hospital. A mass was palpable in the right lower quadrant and x-ray examination and proctoscopy also showed evidence of ulcerative colitis. The patient went downhill notwithstanding the various medical measures employed, including transfusions, sulfonamides and vitamin therapy. During the patient's illness a pseudomembrane could be seen in the throat and *Staphylococcus aureus* could always be isolated from this region. An aphthous stomatitis also was present, which showed temporary improvement with vitamin therapy. Working on the premise that the throat infection might be the source of the acute exacerbation, I gave the patient 1,000,000 units of penicillin over a period of eight days. After one slight episode of bleeding two days after the penicillin was discontinued, the patient began to show evidence of improvement. The throat infection disappeared and her appetite became ravenous, bowel movements decreased and no further bleeding took place. The patient was discharged from the hospital in March 1944 weighing 60 pounds (27 Kg.). I heard from her recently. She is feeling well and now weighs 92 pounds (42 Kg.). I do not say that penicillin cured the ileitis but I do think it saved this patient's life during the acute exacerbation.

DR. EVERETT D. KIEFER, Boston: There is no specific medical treatment for regional ileitis. The medical management to which we referred consists mainly of generally supportive measures, including bed rest for varied periods of time, a bland, low residue, high protein diet and supplemental vitamins in moderately large doses over long periods. Ferrous sulfate was used in cases of anemia, and transfusions were given when the hemoglobin or plasma proteins were low. Sulfonamides were given in a few cases without any definite evidence of benefit as far as we could see. We have had no experience whatever with penicillin.

Somatic Psychologic and Cultural Aspects.—The concept of aging implies a decline in the structural and functional efficiency of the organism. Used in this broadest sense, aging begins at approximately the age of 21. This may be a surprising statement, but there is both experimental and experiential evidence for it. It is not an accident that a champion nearly always is beaten by a younger athlete. Prizefighters or tennis players become champions about the age of 20. There is no doubt that the experience of the champion increases with further practice and so does his judgment; but in so extreme a need for superior performance the aging process is the winner over experience. Likewise it was found that at the age of 28 a flier may be at a definite disadvantage for extreme conditions of high speed flying and that the period of blackout after a dive lengthens from the previous five to eleven seconds.—Mittelman, Bela: *Psychosomatic Medicine and the Older Patient*, from *Mental Disorders in Later Life*, edited by Oscar J. Kaplan, Stanford University Press, 1945.

PENICILLIN IN OTOLOGY

ITS USE IN 511 CASES OF OTITIS MEDIA AND
74 CASES OF MASTOIDITISCOMMANDER CHARLES H. ALLMAN
M.C.-V(S), U.S.N.R.

BOSTON

The origin, preparation and action of penicillin in medicine have been so well described in the literature that I shall not discuss these subjects. Suffice it to say that penicillin is an antibiotic of the greatest importance against certain organisms whether used locally, intramuscularly, intravenously, subcutaneously, intrathecally or by a combination of these methods.

Dosage and methods of administration have not been thoroughly standardized. Cooke and Goldring¹ showed that after intramuscular injections of penicillin the concentration in the circulating blood reached its highest level within thirty minutes. It was still moderately high at the end of one hour and fell rapidly during the second hour but often persisted at lower titer for three to four hours. They found similar results after subcutaneous injection of penicillin.

Swanson and Baker² used penicillin intramuscularly in 15 cases of acute otitis media and locally in the mastoid cavity following mastoidectomy with controlled drainage in 2 cases of mastoiditis with good results. They also used penicillin locally in a case of chronic otitis media when other methods of treatment had failed. The middle ear infection cleared up in eight days, but the perforation of the tympanic membrane remained. In 1 of the mastoidectomies they instilled penicillin (1,000 Oxford units per cubic centimeter) into the mastoid cavity through a rubber tube every six hours. In addition they gave penicillin intramuscularly every three hours. In the other mastoidectomy case they instilled the penicillin (250 Oxford units per cubic centimeter) into the cavity only once a day. They stopped the outer end of the tube.

The Floreys³ advise using penicillin at three hour intervals when giving it systemically in order to maintain the proper blood level. They prefer the intramuscular route as the most practicable. They used penicillin locally in the mastoid cavity following mastoidectomy in 16 cases of acute mastoiditis and in 6 cases of acute exacerbation of chronic mastoiditis. The strength of penicillin was 250 to 500 units per cubic centimeter. It was instilled into the cavity through a short indwelling rubber tube at six hour intervals. The wound was completely closed and controlled drainage maintained. Fourteen of the acute and 5 of the chronic cases healed within ten days. There were no complications in any of their cases.

In this work I have attempted to strike a happy medium, perhaps leaning toward administering too much penicillin rather than too little. When I saw an indication or lack of complete control of the infection, as a rule I increased the frequency of the dosage rather than the size of the dose.

An instance of the use of too little appeared when I first started using penicillin locally in the mastoid cavity. I instilled it into the cavity every six hours, and when the dressings were changed the next two days the incision was not as clean as I expected to see it. After that penicillin was instilled every four hours around the clock routinely for four to seven days, depending on the appearance of the wound, the general condition of the patient and the virulence of the organism.

When using penicillin systemically I began by giving 20,000 Oxford units intramuscularly, and 10,000 units was given by the same method every three hours thereafter day and night until the tympanic membrane and postaural incision were healed.

When using penicillin locally the strength was 500 units per cubic centimeter. Ten cc. was instilled into the mastoid cavity every four hours when it was a large cavity and 5 cc. when it was small. The sodium salt of penicillin was used.

The procedure for the local use of penicillin in the mastoid cavity is as follows: After the mastoid cells and products of inflammation are thoroughly exenterated the mastoid cavity, middle ear and external auditory canal are flushed through and through with warm saline solution and then dried by suction and swabbing. The postaural incision is completely closed except for the entrance of the tube. The tube is secured in the cavity at whatever place in the incision it can lead directly to the antrum without bending.

The tube for instillation of penicillin is 10 inches in length, size 14 French, of soft flexible rubber. The inner end of the tube is placed in the antrum. The outer end of the tube extends out through the dressing to the outer surface of the bandage, where it is secured by adhesive tape. Two inches of the outer end of the tube is covered with sterile gauze, and it is cleaned with alcohol before each instillation. This flexible, soft tube can be used in the cavity even though the dura and lateral sinus are exposed, without causing trauma to either. It can be used when the lateral sinus has been opened if it is properly packed.

Penicillin was used locally for an average of 6.3 days in the cases of mastoidectomy following scarlet fever and 5.1 days in the non-scarlet fever cases, at the end of which time the tube was removed.

The postaural incisions healed by primary intention. After the first few cases the dressings were not changed for four or five days and when removed the inner layers of the dressings were soaked with penicillin and the external auditory canal and incision were completely clear of any infection. Usually the external auditory canal and mastoid cavity contained clear or blood stained penicillin.

The operative patients following scarlet fever ranged in age from 17 to 29 years, with an average age of 19.4 years. These were all males. The non-scarlet fever patients ranged in age from 1½ to 29 years. These were women and children. All of the latter patients were seen over a period of three months following operation and remained normal.

The operative patients following scarlet fever were seen by me or I had reports from them over a period of two months after operation. None of them had recurrences or further difficulty with the ears. About 10 per cent of the total number of scarlet fever patients were treated with penicillin from the onset of the disease.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

2. Swanson, C. A., and Baker, D. C., Jr.: The Use of Penicillin in Diseases of the Ear, *J. A. M. A.* 126: 616-620 (Nov. 4) 1944.

3. Florey, M. E., and Florey, H. W.: General and Local Administration of Penicillin, *Lancet* 1: 387-397 (March 27) 1943.

Undoubtedly the administration of penicillin from the onset of scarlet fever reduces the incidence of ear complications. In a study of 300 patients with scarlet fever in wards giving no penicillin there was an incidence of 10.9 per cent of acute otitis media, while 300 patients in wards giving penicillin to all the scarlet fever patients showed an incidence of only 5.6 per cent otitis media.

BACTERIOLOGY

It was not practical to take cultures of the discharge from the middle ears of the scarlet fever patients or of the first mastoidectomy patients, but cultures were taken from the mastoid cavities of 23 patients at operation. Eleven of these grew *Streptococcus hemolyticus*, 2 of

lococcus aureus hemolyticus in 3 and *Streptococcus hemolyticus* and *Hemophilus influenzae* in 1.

Table 1 gives the analysis of the ear complications occurring in 5,640 cases of scarlet fever. Nine per cent developed acute otitis media, which is about the average incidence or perhaps a little lower than in the usual cases of scarlet fever treated in the routine way without chemotherapy. There were 60 cases of mastoiditis complicating this group of scarlet fever cases, giving an incidence of 1.06 per cent. There were 33 cases requiring mastoidectomy, a percentage of 0.56, and 2 cases of meningitis of otogenic origin.

All of the 511 cases of acute otitis media (table 2) treated with penicillin were complications of scarlet fever. Sixty of the cases of acute mastoiditis were in this group. Twenty-seven, or 45 per cent, of these 60 were cured by systemic treatment with penicillin and did not require surgery. Thirty-three, or 55 per cent, required mastoidectomy. The method of treatment was with penicillin 10,000 Oxford units intramuscularly every three hours night and day. No local treatment was given to the ear other than dry wipes three times a day if discharging and hot saline irrigations for pain. Penicillin was started the instant otitis media was recognized, whether or not the middle ear was discharging. The criteria for a diagnosis of otitis media were pain in the ear, reduction of hearing and the objective findings varying in degree from redness of the tympanic membrane and malleus to bulging and discharge of pus.

Not a single patient had paracentesis. I advise this procedure ordinarily, but conditions were such that it was impossible to do it. As a good surgical principle I definitely advise incision and drainage when there is pent up pus in the middle ear.

There were pronounced and rapid pathologic changes in the structures of the middle ear in these cases, as is usually found in scarlet fever. I had the opportunity of observing hourly changes in the appearance of the tympanic membrane and general condition of 50 of these patients under treatment with penicillin. Some of the tympanic membranes were definitely bulging, discolored and almost black in appearance and in a few hours showed signs of resolving, with return to normal within forty-eight to seventy-two hours. A few cases would clear up from the infection under treatment with penicillin only to develop otitis media again in a few days or even a week or two, but promptly cleared up when penicillin was given again. The drug was continued for two days after all physical signs of otitis media had subsided.

Table 3 gives the analysis of the 33 cases of mastoidectomy following scarlet fever. In 29 of these results were excellent. It required an average of only 8.2 days for healing of the postaural incision and an average of 7.4 days for clearing of the middle ear and healing of the tympanic membrane. This is about one third of the time usually required for these structures to heal in operative mastoiditis following scarlet fever without the use of chemotherapy. There was not a single case of chronic discharging ears following treatment of these cases.

The 2 cases of meningitis were otogenous in origin and were included in the group of 29 mastoidectomies with good results. These 2 were the only cases of intracranial complications in the entire series of ear infections and they were the only cases in which penicillin was not administered from the onset of the middle ear infection. These patients were admitted to the

which were typed and showed type 17. It is reasonable to assume that all of these patients were infected with the same strain of organism.

Typings of the organisms cultured from the throats were done on 3,000 of these scarlet fever patients by the epidemiologist Lieut. Comdr. L. E. Eckels.⁴ All of these showed *Streptococcus hemolyticus* type 17, a potent toxin producer and highly communicable. These organisms were resistant to sulfadiazine in *in vitro* studies. They grew in 125 mg. per hundred cubic centimeters of sodium sulfadiazine in solution. Over 75 per cent of the patients with scarlet fever had received sulfadiazine prophylactically from a few days to two months prior to development of the disease. This was discontinued when it was determined that the organism was resistant to the drug.

Cultures from the mastoid cavities of the 14 non-scarlet fever patients who underwent mastoidectomy grew *Streptococcus hemolyticus* in 4 instances, *Staphy-*

hospital with fully developed meningitis, 1 comatose, the other semicomatose and irrational. Their initial, white blood cell count in the spinal fluid was 6,000 and 5,800. Neither one had received penicillin or other chemotherapy up to this time. Mastoidectomies were done on both patients. They were given penicillin 100,000 units intravenously the first twelve hours, penicillin 15,000 units intrathecally immediately and penicillin 10,000 units intramuscularly every two hours for two days and every three hours thereafter until complete recovery. One patient was given a second dose of penicillin intrathecally on the second day after operation. Penicillin was used locally in the mastoid cavity in the usual way.

As we had no knowledge whether or not the infecting organism was sulfonamide resistant in these 2 patients, they were given sodium sulfadiazine 4 Gm. intravenously every six hours for two days. Both of them recovered consciousness rapidly and were up and about

partly closed with a drain emerging from the lower end of the wound. The comparison as to healing time and hospitalization is striking, being reduced to almost a third of the time when penicillin was used. This table also shows the results of postmastoidectomy treatment with penicillin in 4 cases of chronic mastoiditis. The results in these cases were not remarkable. The postaural incision healed fairly rapidly in all 4 cases but the tympanic membrane healed promptly in only 1 case. In 1 case the discharge from the middle ear continued for three months, at which time it ceased and the tympanic membrane healed. Penicillin was used twice a day in the external auditory canal until it healed. In the other 2 cases of chronic mastoiditis a discharge from the middle ear persists three months after operation in spite of the use of penicillin in the external auditory canal.

There was not a single death in the entire series of cases.

TABLE 3.—Analysis of the 33 Cases of Mastoidectomy Following Scarlet Fever

in ten days. Cultures from the mastoids grew Streptococcus hemolyticus type 17. There was no growth on the cultures from the spinal fluid in either case. Twenty-four hours after the beginning of treatment of these 2 patients their spinal fluid showed less than 0.5 unit of penicillin per cubic centimeter of fluid.

Three of the 4 patients treated with only fair results (table 3) had their lateral sinuses opened and packed at operation. Possibly this was the reason why healing did not occur and the infection clear up sooner although penicillin was administered in the usual way. There was no obvious reason for the fourth case in this group not doing well. The postaural wound broke down on the fourth day after operation, drained pus profusely and did not heal for twenty-seven days.

Table 4 gives the analysis of 17 mastoidectomies on the patients with non-scarlet fever mastoiditis. Ten of these were operated on for acute mastoiditis and penicillin was administered in the usual way. All of them healed rapidly, requiring an average of only 6.3 days for the postaural incision and tympanic membrane to heal. Postoperative hospitalization lasted an average of 7.1 days.

Three of these patients were operated on for acute mastoiditis before I started using penicillin. The mastoid cavity was packed with iodoform gauze, the wound

Engler⁵ made a survey of otitis media in scarlet fever at the Cleveland City Hospital over the ten year period from Jan. 1, 1930 to Jan. 1, 1940. During this period there were 8,229 cases of scarlet fever admitted. There

TABLE 5.—Comparison of the Ear Complications in Engler's Survey of 8,229 Cases of Scarlet Fever and Author's Group of 5,640 Cases

	Engler's Survey				Author's Cases			
	Number of Cases	Per Cent	Per Cent of Otitis Media Cases Requiring Mastoidectomy	Mortality, per Cent	Number of Cases	Per Cent	Per Cent of Otitis Media Cases Requiring Mastoidectomy	Mortality
Otitis media....	798	9.7	19.3	3.7	511	9.0	6.4	0

were 798 complications of otitis media, an incidence of 9.7 per cent; 154 cases of mastoiditis, an incidence of 1.9 per cent, and 14 cases of intracranial complications, an incidence of 0.17 per cent (table 5). In 19.3 per

5. Engler, C. W.: Otitis Media in Scarlet Fever: A Survey of Cases at Cleveland City Hospital for Past Ten Years, Ohio State M. J. 37: 139-143 (Feb.) 1941.

cent of his 798 cases of otitis media mastoiditis developed and in 1.8 per cent intracranial complications developed. The mortality rate in his survey of otitis media cases was 3.7 per cent and in the cases of mastoiditis 5.8 per cent. The first seven years of Engler's survey period was previous to the advent of chemotherapy for ear diseases, and during this time mastoiditis developed in 20.2 per cent of the cases of otitis media, while during the last three years of his survey sulfanilamide was administered in the otitis media cases and mastoiditis developed in only 14 per cent.

Table 5 gives a comparison of the results in this series of cases I have reported with those of Engler's survey. In noting the difference in morbidity and not a death among my cases it must be realized that the incidence of ear complications following scarlet fever is greater in young children from the ages of 1 to 8 years than in adults. In his survey 76.4 per cent of all the otitis media cases were in this age group. Nevertheless to observe these sick men (and most of them were very sick) from day to day and see the pronounced and rapid improvement, one must give much credit to penicillin. I am sure that some of them would have died and the morbidity would have been much greater without its use.

SUMMARY

Penicillin was used intramuscularly in the treatment of 511 cases of scarlet fever otitis media. It cured 27 cases of scarlet fever mastoiditis without surgery. It was used intramuscularly and locally in 33 cases of scarlet fever mastoiditis requiring surgery, in 2 of which meningitis was present. It was administered by the same methods in the postoperative treatment of 14 non-scarlet fever cases of mastoiditis. Ten of these were acute and 4 were chronic. Penicillin kept the morbidity to a minimum and there were no deaths.

✓ CYANOSIS IN INFANTS CAUSED BY NITRATES IN WELL WATER

HUNTER H. COMLY, M.D.
IOWA CITY

Two examples of a previously unrecognized condition which may be confused with congenital heart disease are cited in this report. The condition may occur anywhere in rural areas where well water is used in infant feeding.

REPORT OF CASES

CASE I.—C. H., a white female baby, was born two weeks before the expected date by cesarean section because of toxemia of pregnancy, which had been severe for one month. The birth weight was 3,870 Gm. (8 pounds 8 ounces). There was no known neonatal distress. On the twelfth day after birth, when she left the hospital, she weighed 3,720 grams (8 pounds 3 ounces). The formula she was receiving at that time was evaporated milk 210 cc. and water 540 cc. with 30 Gm. of a dextrin-maltose preparation.

From the Department of Pediatrics, State University of Iowa College of Medicine.

Dr. Robert L. Jackson admitted the first patient to the Children's Hospital and gave the author the opportunity to study his patient. The second patient was admitted, and the diagnosis was made, by Dr. Julia McElhinney.

The methemoglobin determinations in the 2 cases were carried out by Mr. George Dubey Jr., research assistant in the Department of Internal Medicine, State University of Iowa, using the method of Michel and Harris (*J. Lab. & Clin. Med.* 25: 445 [Feb.] 1940).

The analyses of the samples of well water were made by Dr. J. Garth Johnson, principal water analyst, State Hygienic Laboratory, Iowa State Department of Health. The nitrate determinations were carried out by means of the phenol-disulfonic acid method. Methods for Examination of Water and Sewage, 18th ed., American Public Health Association, Lancaster, Pa., Lancaster Press, Inc., 1936, p. 48).

She was admitted to a local hospital at 18 days of age because of vomiting, excessive crying and failure to gain weight. After admission an acidified skim milk formula was substituted and, because diarrhea followed, 1 teaspoon of a kaolin-pectin powder was added to each bottle of formula. The baby was discharged at the age of 27 days, having gained 360 Gm. (12 ounces).

She was seen again because of diarrhea at 31 days of age, at which time it was suspected that she might be allergic to the milk formula. A proprietary food mixture with soy bean powder as its principal ingredient was prescribed. The formula consisted of 80 Gm. of this mixture and 840 cc. of boiled water.

Two days later, after nine to twelve hours of irritability, the infant was noticed to be decidedly cyanotic and drowsy. So alarming were the signs that the parents rushed the baby again to the local hospital. Physical examination at that time revealed no evidence of pneumonia, atelectasis or pneumothorax; the heart sounds were good and the temperature was normal. A defective oil burner was in use in the home, and although the picture was not consistent with carbon monoxide poisoning a peculiar gaseous poison producing methemoglobinemia was suspected. Preliminary treatment with oxygen for thirty minutes resulted in no change. Therefore 1 per cent methylene blue, 1.1 cc. for each kilogram of body weight, was administered under the scalp, and the local area was massaged vigorously. Within thirty minutes the color, respirations and heart rate were normal. The cyanosis did not recur in the hospital, and the baby was discharged in a week, asymptomatic and taking the soy bean formula satisfactorily.

Forty-eight hours later the baby again was taken to the hospital with similar signs, and the same treatment was employed. (This time the aforementioned oil burner had not been in use.) She was hospitalized for sixteen days and at the time of discharge weighed 4,545 grams (10 pounds), had normal stools and was taking her soy bean and water formula in a normal, healthy fashion.

Two days later the parents suspected the onset of the same condition and returned with her to the hospital. This time the signs evidently were not convincing, for the baby was not admitted or treated. The parents were assured that she was well and were told to take her home.

Much to every one's disappointment, the baby was readmitted the next day suffering the worst attack of any. Two hours were required for the methylene blue treatment to relieve her distress.

It was realized that the only significant change in the infant's environment from hospital to farm home was in the water. Sulfhemoglobinemia being a remote possibility, the water was analyzed but no sulfides were found. The water was not tested bacteriologically. Nevertheless, the parents were warned not to give any more well water, and a formula of acidified whole milk was substituted.

The infant's father was dissatisfied with this incomplete explanation and also was loath to accept the possibility that his daughter was abnormal. Therefore arrangements were made to have her admitted to the Children's Hospital of the University of Iowa. The father believed that a peculiar reaction occurred between the well water and the soy bean preparation, producing a poison which caused her distress. Hence he asked the admitting physician if it would be desirable to bring samples of the water and powdered formula to the hospital for analysis. An open minded attitude on the part of the latter in accepting this "cock and bull" theory as plausible resulted in the father's bringing the water, which yielded the answer to the problem.

Physical examination on admission to the Children's Hospital revealed no abnormalities. The urine was normal. The red blood cell count was 3.2 million, with 11 Gm. of hemoglobin. The white blood cell count was 6,750, with a normal differential count. The blood Wassermann and Kline reactions were negative. A roentgenogram of the chest showed no abnormality. An analysis of the baby's blood for methemoglobin yielded a high normal value¹ of 0.18 Gm. for each hundred cubic centimeters.

1. Paul, W. D., and Kemp, C. R.: Methemoglobin: A Normal Constituent of Blood, *Proc. Soc. Exper. Biol. & Med.* 56: 55-56 (May) 1944.

Reports in the literature of infantile methemoglobinemia caused by bismuth subnitrate suggested that nitrates might be the causative agent in this case. It was thought that the well water might contain toxic amounts of nitrates. An analysis of the water confirmed this suspicion. An unboiled sample of water had a nitrate nitrogen value of 140 parts per million, which is equivalent to 0.619 Gm. of nitrate ion to the liter. One Gm. of potassium nitrate (saltpeter) in a liter of water approximates this nitrate ion concentration. The sample contained 0.4 mg. of nitrite ion to the liter.

A second sample of water collected from the well several days later and boiled the same length of time as that given the baby contained 0.530 Gm. of nitrate ion to the liter, which approaches the amount found in the first sample analyzed. Culture of water from the well revealed the water to be highly polluted, as an M. P. N. (most probably number of coliform organisms for each hundred cubic centimeters) of 240 was obtained. U. S. Public Health Service drinking water standards allow an M. P. N. of not more than 5.

The baby was sent home on the fifth hospital day, receiving a half-skimmed, acidified milk formula to which no water was to be added. When seen by the family physician at the age of 4 months, no evidence of any permanent central nervous system damage from cerebral anoxia was found.

CASE 2.—S. M., a white female baby, was born normally after an uneventful pregnancy. The birth weight was 3,400 Gm. (7 pounds 8 ounces). There was no neonatal distress, and she had almost regained her birth weight when she left the

*Decrease in Methemoglobin Content After Administration
of Methylene Blue*

Sample	Time	Methemoglobin Content
1	4:30 p. m.	2.65 Gm. for each 100 cc.
2	7:20 p. m.	2.72 Gm. for each 100 cc.
3	9:10 p. m.	2.70 Gm. for each 100 cc.
	10:13 p. m.	Methylene blue
4	10:45 p. m.	0.18 Gm. for each 100 cc.
5	11:54 p. m.	0.25 Gm. for each 100 cc.
6	11 a. m. (next day)	0.22 Gm. for each 100 cc.

hospital on the ninth day after birth. A formula of evaporated milk, water and corn syrup was prescribed. The baby developed diarrhea with eight to ten loose, green stools a day but did not vomit. At 27 days of age she became "blanched out," cyanotic and drowsy and was taken to the family physician. On this day she weighed 4,140 Gm. (9 pounds 2 ounces) in her clothing. The physician informed the parents that they had a blue baby. After an adjustment of the formula was made, the baby was sent home. At 31 days of age a formula of evaporated milk 210 cc., boiled-water 510 cc. and corn syrup 45 cc. was given.

The cyanosis never again became so noticeable as on the twenty-seventh day after birth, but it remained obvious and caused the parents to bring the baby to the Children's Hospital at the age of 38 days. Physical examination on entry revealed that the infant was well developed and well nourished, with a moderately cyanotic skin. Crying intensified the cyanosis. The fontanel was soft. The heart rate was not rapid, and no murmur was heard. The chest was clear to percussion and auscultation. Neither the liver nor the spleen seemed enlarged. The buttocks were moderately excoriated, attesting the persistent diarrhea. Laboratory data included negative blood Wassermann and Kline reactions. The Haden-Hausser hemoglobin value was 13 Gm., the red blood cell count was 2.95 million and the white blood cell count was 10,000, with a normal differential count.

Blood samples were collected at 4.30 p. m. (just before a feeding), at 7:20 p. m. and at 9:10 p. m. At 10:13 p. m. 0.6 cc. of a 1 per cent solution of methylene blue was administered intravenously (a dosage of approximately 1.5 mg. for each kilogram of body weight). Blood samples were then collected at 10:45 p. m., at 11:45 p. m. and at 11 a. m. the

next day. These were taken immediately to the laboratory, and within one-half hour in each case the quantitative determination of methemoglobin was carried out. The results are given in the table.

The first three samples of blood when drawn were of a peculiar chocolate color. One-half hour after the methylene blue was given, the blood was normal in color. The change in the infant's appearance was especially dramatic. Unfortunately, accurate measurements of pulse and respiration were not made, but two observers noted that the infant's cry and behavior were more vigorous and that the skin color was excellent.

A sample of the well water used in preparing the infant's formula had a nitrate nitrogen value of 90 parts per million, which is equivalent to 0.388 Gm. of nitrate ion to the liter. This is roughly two-thirds the amount present in case 1. The nitrite ion content was 1.314 mg. to the liter. An attempt to analyze the formula to determine the exact amount of nitrate ion contained was unsuccessful because of caramelization. It would appear that the baby ingested approximately 0.20 Gm. of nitrate ion a day, roughly equivalent to $\frac{1}{3}$ Gm. of potassium nitrate.

The well water was tested bacteriologically and found to be as badly polluted as the well in case 1.

Samples of blood from the mother and father, both of whom drank the unboiled well water, revealed no abnormal quantities of methemoglobin.

The baby was sent home, asymptomatic, on the second hospital day and has continued to do well. No further attacks of cyanosis have occurred.

COMMENT

Since these patients were seen by us, the Iowa State Hygienic Laboratory has received from similar wells five other samples of water containing large amounts of nitrates. The analyses were made because infants who drank the water were cyanotic. Four of these five definitely became blue after formulas containing the water were given. In the fifth case an accurate history was not obtainable; the infant in question was noted to have a "rattle in the chest," and he experienced difficulty in breathing. Thus it is possible that methemoglobinemia existed alone, that true anoxicemic cyanosis was present or that the two conditions coexisted. This last infant had a bad start in life and was hospitalized at the age of 10 months at the Children's Hospital because of chronic diarrhea, stomatitis, bronchitis and malnutrition. One can only speculate as to the effect of prolonged ingestion of such water by infants.

Dr. Morgan J. Foster² of Cedar Rapids, Iowa, states that he has seen 5 similar cases in his practice. All the infants tended to be irritable and had diarrhea. Four were treated with methylene blue, and 1 infant died before the methylene blue treatment was known. From his records he noted that all the infants were receiving diluted milk formulas and that they came from farms in southeastern Iowa.

Dr. Roland Stahr,² formerly of Fort Dodge, Iowa, reported 5 cases of idiopathic cyanosis at the annual meeting of the American Academy of Pediatrics in San Francisco during May 1941. All of the infants had gastrointestinal disturbances. Twin infants, 26 days old, had mild cyanosis while receiving a diluted milk formula. Because of diarrhea a dried skim milk and water mixture was given. Deep cyanosis followed within a few hours in both infants. Methemoglobinemia was proved to be the source of the cyanosis. It cannot be stated definitely that these babies received well water, but 4 of the patients lived in northern rural Iowa.

2. Personal communication to the author.

Schwartz and Rector³ reported the occurrence of methemoglobinemia of unknown origin in an infant aged 2 weeks. This baby was receiving a diluted evaporated milk formula. Their report does not state whether or not the infant came from a farm home where well water was used, but the general picture is similar. The infant was treated effectively with methylene blue.

Members of our staff, after having learned of this condition, saw 2 babies who were cyanotic without obvious cause. Both infants improved when the well water was removed from the feedings. In retrospect it was realized that 2 other infants, both from the same family, had been seen in consultation because of a peculiar cyanosis. Checking back, it was found that they both were taking evaporated milk feedings diluted with well water. Both of them had recovered when feedings containing less well water were given.

Thus it would seem that this condition is not rare, and a discussion of certain of its aspects may be helpful:

Cyanosis is due ordinarily to the presence of unusually large amounts of reduced hemoglobin in the subpapillary venous plexuses of the skin. Conditions such as cardiac or pulmonary disease, polycythemia or occlusions of major vessels in the extremities commonly result in cyanosis.

Abnormal compounds of hemoglobin, possessing differing absorption spectrums, may impart a peculiar hue to the skin. Thus, carbon monoxide reacts with hemoglobin to form carboxyhemoglobin, which in sufficient amount produces the striking "cherry red cyanosis." Likewise, methemoglobinemia may be associated with an unusual brown-gray skin color, sufficiently different from the color of reduced hemoglobin to arouse the suspicion that the primary difficulty is not common anoxemia.

Methemoglobinemia may follow the administration of such chemicals as aniline, nitrophenol, sulfanilamide, potassium chlorate and nitrates. That nitrates may be associated with serious or fatal methemoglobinemia in infants has been realized since bismuth subnitrate first was used as a contrast medium by roentgenologists. Roe⁴ in 1933 reported the death of a 1 month old infant with diarrhea who had received 0.6 Gm. of bismuth subnitrate every two hours "until the stools became black." Cyanosis occurred in twenty-four hours. Thirteen Gm. of the drug was given in forty-four hours, and despite oxygen therapy death occurred sixty hours after the drug first was given. Roe emphasized the dangers inherent in the use of this bismuth compound and recommended the use of bismuth subcarbonate in the treatment of diarrhea.

Nitrate methemoglobinemia in adults has been reported less frequently. Eusterman and Keith⁵ administered ammonium nitrate orally for diuretic purposes to a large series of adults; 2 patients developed methemoglobinemia. In 1, extreme cyanosis occurred when 54 Gm. was given in eight days. These workers gave ammonium nitrate intravenously to dogs and failed to produce methemoglobinemia. They concluded that the nitrate ion was transformed to nitrite by some abnormal metabolic process present in the 2 patients, both of whom had intestinal stasis.

That the nitrite ion will bring about methemoglobinemia is well established. In the treatment of cyanide poisoning Chen, Rose and Clowes⁶ showed sodium nitrite (administered intravenously) to be an effective agent for producing methemoglobinemia. Greenberg, Lester and Haggard⁷ demonstrated *in vitro* that one molecule of a nitrite ion reacts with two molecules of hemoglobin to form methemoglobin. In acid mediums the conversion to methemoglobin occurs rapidly; in neutral or alkaline solutions the conversion is delayed.

Van den Bergh⁸ in 1905 indicated that nitrites could be formed in the bowel from nitrates and that absorption of the nitrite ion was encouraged by the presence of damaged intestinal mucosa. ZoBell⁹ demonstrated *in vitro* that many organisms commonly found in the gastrointestinal tract were capable of converting nitrates to nitrites.

Thus it would seem that the methemoglobinemia of the infants of this report was produced as the result of the ingestion of well water containing large amounts of nitrate compounds. The nitrate ion was probably converted to the nitrite ion in the intestine by bacterial action. The nitrite ion, so formed, was absorbed and reacted with hemoglobin to form methemoglobin. The amount of nitrites already present in the well water was probably of little significance.

Although the fact that the infant possesses much less oxidizable hemoglobin than the adult is probably the most important single factor in making him more susceptible to nitrate compounds, other factors may conspire to render nitrates more toxic. Thus the bacterial flora may include more nitrate converters than in the adult. Gastrointestinal disturbances in infants are more common than in adulthood, and the delicate mucosa may be injured more easily. In the infant the high fluid turnover and more rapid circulation may favor more complete absorption of the nitrite ions from the intestine. It is possible that the nitrite ions may be more firmly bound by infantile hemoglobin (which differs from adult hemoglobin) because of immaturity of certain enzymes. Stevenson¹⁰ has shown that carbonic anhydrase, to name one such enzyme, is present in relatively small quantities in the infant. Further the limited excretory power of the immature kidney may favor retention of the nitrite ion.

The 2 infants who were the subjects of this report had gastrointestinal disturbances. Whether a separate cause brought about the diarrhea and vomiting in each case or whether the nitrate salts themselves or other constituents of the putrid water incited the diarrhea cannot be ascertained. Since the gastrointestinal symptoms were almost universal and in certain cases became more severe as the formulas were further diluted with the well water, it seems likely that the cause for the whole difficulty may have been in the water. It cannot, however, be stated positively that gastrointestinal disturbances always accompany this condition, as there was no such complaint by a patient seen recently.

Neither parent of the baby in case 2 had abnormal methemoglobinemia. It is clear that the nitrate intake

was too low for a significant amount of hemoglobin to become converted. A minimal degree of methemoglobinemia is physiologic¹ and its reduction to hemoglobin is probably a continuous process. With intermittent, relatively low dosage a clinically detectable level could hardly be built up in the adults, whereas in the infant a relatively large, constant and regularly timed intake may, under certain circumstances, build up a fatal level.

Wendel¹¹ in 1939 studied the effect of methylene blue in the sodium nitrite-induced methemoglobinemia of dogs. At his suggestion Hartmann and his associates¹² used the dye in the prophylaxis and therapy of sulfanilamide-induced methemoglobinemia. These workers showed that a single intravenous dose of from 1 to 2 mg. for each kilogram of body weight would rapidly clear the cyanosis. Sixty-five to 130 mg. of the dye for each kilogram of body weight given every four hours by mouth would prevent the cyanosis of sulfanilamide administration. They warned that occasionally vomiting, diarrhea, headache and tinnitus occurred when methylene blue was given by mouth. Perivascular infiltration may lead to painful induration or even to necrosis. No serious reactions were encountered.

The mechanism of action of methylene blue in effecting the rapid transformation is not clearly understood. Paradoxically, in high concentration it oxidizes the ferrous iron of reduced hemoglobin to the ferric iron of methemoglobin, as do nitrites. This function has been used in the treatment of cyanide poisoning. In lower concentrations the drug seems to catalyze the physiologic reduction of methemoglobin by the body. It has been suggested by Wendel¹¹ that the leuko- or reduced form of the dye is formed in the erythrocytes and other body cells by certain cellular enzymes. This form may then act catalytically to promote the reduction of methemoglobin.

The high nitrate water which the cyanotic infants ingested came from very undesirable wells. In many cases the wells were old, dug rather than drilled, had inadequate casings or none at all, and were poorly covered so that surface water, animal excreta and other objectionable material could enter freely. In every one of the instances in which cyanosis developed in infants the wells were situated near barnyards and pit privies. Some of the wells had trees growing nearby, and the roots had penetrated or broken down the casings. In four of the five the water was highly contaminated with coliform organisms, but in the fifth case the water was bacteriologically safe for drinking purposes. This point serves to emphasize the fact that a well may be acceptable with respect to bacterial content and yet be potentially dangerous for use in infant feeding. It is not difficult to visualize how such a situation may arise: water seeping from barnyards and privy pits, heavily laden with bacteria and dissolved nitrogenous materials, becomes increasingly purified by passage through the soil. Certain soil bacteria have the power to oxidize ammonia and other nitrogen compounds to nitrates. The solution of nitrates so formed, rendered free from coliform organisms by the competitive growth

of the hardy soil bacteria, may then enter subsurface water channels leading directly into wells used for drinking purposes. In periods of low water table the passage of the water through the earth may be slower. This slow passage may allow more nitrate to be leached from the soil and become concentrated in the wells until toxic amounts are present.

The nitrate content of water taken from wells in Iowa varied from zero to 125 parts per million (as nitrate nitrogen) in a survey made of 2,000 samples taken from domestic and municipal wells in 1934 and 1935.¹³ The highest nitrate nitrogen content on record in the State Hygienic Laboratory is 567 parts per million.¹⁴ The nitrate nitrogen of the water given to the infants varied from 64 to 140 parts per million, and the severity of symptoms seemed to parallel roughly the amount of nitrate present. Although no definite statement can be made, it would seem advisable to recommend that well water used in infant feeding possess a nitrate content no higher than 10 or, at the most, 20 parts per million.

Since Jan. 1, 1945, of 91 samples of water from dug wells sent for routine analysis by their owners 18, or roughly 20 per cent, had nitrate nitrogen values above 65 parts per million. These waters might be seriously toxic to infants if fed in any appreciable amounts. Fifty-one samples, or 56 per cent, contained amounts of nitrate greater than 10 parts per million.¹⁵

This, doubtless, is not a fair sampling of the domestic wells in Iowa, as all the water was sent in because, for one reason or another, its purity was doubted. It does serve to show, however, the frequency with which high nitrate values will be found if the water is suspected for any of the usual reasons.

All but one of the wells with high nitrate water were dug wells, most of which probably had defective casings. All but one of the samples of water causing symptoms in infants came from similar wells. In the latter exception the well was drilled but the condition of the casing was in doubt.

The bacteriologic data accumulated from these wells are typical of those commonly found. From 75 to 77 per cent of the privately owned wells in Iowa are contaminated, as evidenced by the presence of large numbers of coliform organisms.¹⁵

From the foregoing discussion it is obvious that artificial feeding of the farm baby is fraught with potential danger, and it serves to emphasize the desirability of breast feeding whenever possible. Certainly, in view of the deplorable condition of most wells, the physician should make inquiry regarding the source of water which the infant will receive. (A valuable booklet setting forth the sanitary standards for hand-pumped wells is obtainable.¹⁶) That all such drinking water should be boiled is clear. However, it must be understood that even boiling the water may not render it safe. If the source is under suspicion, the physician will do well to prescribe a formula containing relatively little water. Thus, a diluted whole milk feeding would be preferable to a diluted evaporated milk mixture. A dried milk and water formula would be most dangerous, whereas an acidified, boiled, undiluted milk feeding would provide the greatest possible margin of safety.

SUMMARY

Cyanosis due to methemoglobinemia may occur in infants with gastrointestinal disturbances who receive boiled water which comes from poorly constructed dug or drilled farmyard wells with defective casings. The water may contain large amounts of nitrate compounds which, when ingested, are converted by bacterial action to nitrites. The nitrite ion is absorbed and oxidizes hemoglobin to methemoglobin.

The intravenous administration of methylene blue in the dosage of 1 to 2 mg. for each kilogram of body weight promptly relieves the infant's cyanosis and distress.

The condition is not rare. Ample opportunity for its frequent occurrence exists. The condition may occur in any degree of severity, either acutely, subacutely or chronically. It may possibly lead to a fatal outcome. In all probability certain instances are incorrectly interpreted as being due to congenital heart disease.¹⁷

LESIONS OF SMALL INTESTINE PRODUCING MASSIVE HEMORRHAGE

WITH SYMPTOMS SIMULATING 'PEPTIC ULCER

HARRY L. SEGAL, M.D.

W. J. MERLE SCOTT, M.D.

AND

J. S. WATSON, M.D.

ROCHESTER, N. Y.

Neither pronounced melena alone nor pain alone caused by lesions in the jejunum or ileum is too unusual. There are many such reports in the literature. However, the combination of these two symptoms presenting a picture simulating peptic ulcer but produced by pathologic conditions in the small intestine beyond the duodenum has not been emphasized in the literature. Articles by Dudley¹ and Klingenstein² are the only two we noted that stressed such a syndrome. Thus, it seems of value to report our experience with this combination of melena and postprandial pain due to lesions of the small intestine beyond the duodenum even though our cases have been few in number.

During the past two years we have encountered 3 such patients. Two of these patients had repeated hospital admissions, at which times they were treated medically for bleeding duodenal ulcer. The third patient had only one hospital admission and was suspected at first of having a bleeding peptic ulcer. All of these patients were operated on and each was found to have a lesion of the small intestine as the cause of the massive hemorrhage and the symptoms simulating those of peptic ulcer.

17 Since this article was submitted for publication an intensely cyanotic infant was admitted to the Children's Hospital. Because he seemed to be in no particular distress, the methylene blue treatment was withheld. Twenty-four hours after the well water feedings were stopped the baby's color was normal.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

From the Department of Medicine of the Genesee Hospital and the Departments of Medicine and Surgery of the Strong Memorial and Rochester Municipal Hospitals of the University of Rochester School of Medicine and Dentistry.

REPORT OF CASES

CASE 1.—A R., a woman aged 49, seen at the Genesee Hospital in 1940, had had an appendectomy and a right tubal pregnancy. The first episode of tarry stools occurred in 1932 at which time a gastrointestinal series showed an inconstant irregularity in the duodenal bulb, and the oral cholecystogram revealed a calculus in the gallbladder. The diagnosis was duodenal ulcer with hemorrhage and the patient was placed on an ulcer regimen. Following this admission the patient

Fig 1 (case 1).—Sections of carcinoid tumor of the jejunum. a, intact mucosa and submucosa with the carcinoid cells in the muscularis layer. b, higher magnification of the carcinoid cells in the muscularis layer. The sections are slightly reduced from photomicrographs with a magnification (a) of 100 diameters and (b) of 430 diameters.

had six more hospital admissions, four of which were for episodes of severe melena with pronounced anemia. The stools varied from reddish to a tarry color. The patient also complained of postprandial epigastric distress. She was placed on an ulcer regimen for each one of these episodes, with apparent improvement. Surgery was advised but refused. Blood findings during episodes were as low as hemoglobin 4 Gm. and red blood cells 1,728,000. Gastric analysis shortly after hemorrhage

revealed: Fasting, no free acid; one-half hour after alcohol, free acid 28 units, total acid 38 units. During normal interval: fasting, free acid 20 units, total acid 36 units; one hour after alcohol, free acid 35 units, total acid 89 units. The last admission was in 1940 for gastric surgery, the preoperative diagnosis being duodenal ulcer. Operation was performed by Dr. F. N. Zuck, who described the findings as a mass in the jejunum the size of a large plum, with an ulcerated area on its intraluminal surface. A large adjacent mass of infiltrated lymph nodes was present. The gallbladder was surrounded by dense fibrous adhesions which bound the gallbladder to the pylorus and first portion of the duodenum. Two large marble sized calculi were palpated. The stomach and duodenum appeared normal. The mass was resected and an end to end anastomosis was performed. Microscopic examination showed this tumor to be a carcinoid with infiltration into the adjacent lymph nodes (fig. 1).

The patient was readmitted to the hospital in 1942 because of gallbladder pain. A cholecystectomy was performed and many adhesions were found in the abdomen at the site of the previous operation. No evidence of recurrence or metastases was present.

This woman was seen over a period of eight years for repeated episodes of severe gastrointestinal bleeding with postprandial pains simulating those of peptic ulcer. The gastrointestinal series showed an inconstant irregularity in the duodenal cap. With such a syndrome plus the roentgenologic findings the most logical diagnosis seemed to be duodenal ulcer with repeated episodes of hemorrhage. The findings proved to be a carcinoid of the jejunum. The irregularity in the duodenal cap was caused by adhesions from the diseased gallbladder.

If a Levine tube had been passed during the acute episode of bleeding and had failed to reveal evidence of gross bleeding, the finger of suspicion might have moved away from duodenal ulcer. Close analysis of the postprandial pains did not show them to be typical. However, duodenal ulcers, especially in women, do not always provide typical symptoms. The other confusing element was the presence of gallbladder disease. Gastric analysis was not of value—it was low in the anemic period but high in the interval.

CASE 2.—R. G., a man aged 52, seen at the Strong Memorial and the Rochester Municipal hospitals in 1941, had had pulmonary tuberculosis, for which a left apical paraffin pack had been performed. The first admission to the Rochester Municipal Hospital was in November 1941. The patient's history was that of an ulcer since 1940 with two previous episodes of bleeding. He had definite postprandial pains relieved by food. Diagnosis at this time was duodenal ulcer with bleeding; old pulmonary tuberculosis. Blood examination revealed hemoglobin 5.5 Gm, red blood cells 1,810,000, white blood cells 9,600, nonprotein nitrogen 39 mg. per hundred cubic centimeters. The stools became negative for occult blood. The gastrointestinal series revealed the stomach and duodenal cap to be normal. The upper portion of the jejunum on the first roentgenologic examination showed a constricted area which suggested some type of lesion. This area was reexamined and the defect could not be demonstrated. On Jan. 21, 1942 a recheck gastrointestinal series revealed some narrowing of the duodenal cap, which was interpreted as probably a healed duodenal ulcer. The lesion previously seen in the small intestine was not noticed. On Feb. 13, 1943 the patient was readmitted to the Strong Memorial Hospital because of weakness and the presence of tarry stools. Pains were no longer relieved by food, and a 5 pound (2.3 Kg.) weight loss had occurred. The gastrointestinal series showed no lesion in the duodenum. Gastric analysis Feb. 20, 1943 revealed no free hydrochloric acid after alcohol. On this admission the diagnosis of duodenal ulcer was discarded and suspicion was directed to gastritis, Meckel's diverticulum or a lesion of the small

intestine. Symptoms simulating duodenal obstruction developed and the gastrointestinal series on March 25 revealed a filling defect in the upper jejunum just beyond the duodenojejunal flexure (fig. 2). This was present in the same location as previously noted in 1941. The impression now was an intrinsic lesion of the upper jejunum which might be carcinoma. Operation was performed by one of us (W. J. M. S.) on May 5. A mass the size of an orange which extended into the mesentery was present in the first part of the jejunum. This mass was firm and nodular and appeared malignant. The tumor with the adjacent jejunum and mesentery was removed and an end to end anastomosis was performed. Microscopic diagnosis was carcinoma of the jejunum with invasion of the lymph nodes (fig. 3). Symptoms of obstruction occurred in August, and exploration on September 14 revealed the jejunum to be rotated and twisted by an inoperable mass. The adhesions were divided, resulting in release of this partial obstruction

Fig. 2 (case 2).—Constricted area in the upper jejunum produced by the carcinoma.

This represents another instance of repeated episodes of gastrointestinal hemorrhage and postprandial pains simulating peptic ulcer. The patient had repeated hospital admissions over a period of two years because of the recurrence of massive bleeding, at which times he was treated medically for duodenal ulcer with bleeding. Eventually he developed symptoms of obstruction, which still could have fitted the picture of a duodenal ulcer which had become obstructed. A gastric analysis showed no free hydrochloric acid, and it was then realized that the man had some lesion other than duodenal ulcer. The final gastrointestinal series definitely showed a constricting lesion in the jejunum near the duodenojejunal flexure area, and the diagnosis was changed to possible carcinoma of the jejunum.

The original gastrointestinal series in 1941 showed some changes in the same part of the jejunum, which unfortunately was not demonstrable in a recheck roentgenologic examination. If at that time a gastric

analysis had been done it might have shown no free hydrochloric and might have made one aware that a peptic ulcer was not responsible for this syndrome. This might have led to an exploration at the first

Fig 3 (case 2).—Section of carcinoma of jejunum, reduced from a photomicrograph with a magnification of 100 diameters.

admission. Undoubtedly then there would have been a better chance for a cure. The use of a Levine tube during the bleeding episode, by failing to reveal gross blood, might also have turned the diagnosis away from duodenal ulcer.

Fig 4 (case 3).—Section of hemangioma of ileum, reduced from a photomicrograph with a magnification of 25 diameters.

CASE 3—J. F., a man aged 23, who entered the Strong Memorial Hospital on Jan 12, 1943, had had epigastric pains four or five weeks previous to admission; the exact relation

to meals was not noticed. Two weeks before admission the patient thought he had swallowed a small fragment of glass present in his food. The day before admission he suddenly passed reddish and then tarry stools following a hearty meal. He vomited once but did not notice any blood in the vomitus. He had repeated passage of reddish and tarry stools.

Physical examination showed that he was well developed and in mild shock. Hemoglobin was 8.9 Gm., red blood cells numbered 2,670,000, white blood cells 8,700, neutrophils 82 per cent, monocytes 8 per cent, lymphocytes 10 per cent. The provisional diagnosis was duodenal ulcer with hemorrhage or possibly a bleeding ulcer in a Meckel's diverticulum. The patient was put on hourly feedings of milk with a colloidal suspension of aluminum hydroxide. Bleeding episodes continued together with some epigastric pain, noncharacteristic in type. To assist in the differential diagnosis, a gastrointestinal series was given which showed a normal stomach and duodenal

Fig 5 (case 3).—Normal appearance of stomach and duodenal cap during episode of bleeding.

cap without evidence of any irritation or spasm (fig. 5). Because of the negative gastrointestinal series the inconclusive history and lack of definite blood in the vomitus, it was felt that the bleeding was not accounted for on the basis of a duodenal ulcer but more probably on the basis of an ulcer in a Meckel's diverticulum or an ulcerated lesion of the intestine below the duodenum. The patient continued to show evidence of blood loss in spite of repeated transfusions. His red count dropped to 1,730,000 red cells and hemoglobin to 6 Gm. The patient's prothrombin time was only 20 per cent greater than normal. His bleeding time was two minutes.

On January 23, eleven days after admission, an exploratory laparotomy was performed by one of us. His systolic blood pressure when he went to the operating room was down to 70 mm. After a large transfusion it came up to 94/60, at which time the operation was begun, while blood was given him continuously during the operation. When the abdomen was opened no gross lesion was found to account for the bleeding. The purple color of the intestinal contents could be seen in the colon and about one-half way up the small

intestine. After it had been found that the stomach and duodenum appeared normal both on inspection and on palpation and that a Meckel's diverticulum was not present, the intestine was examined inch by inch, beginning at the ileocecal valve and continuing upward to the ligament of Treitz. A nodule about 3 mm. in diameter was found in the antemesenteric border of the upper part of the ileum. A short distance above this point the purplish color of the intestinal contents stopped and the intestine showed its normal gross appearance. At first it was felt that the small nodule could be moved about 1 cm. up and down the intestine and that it probably was a polyp. At this time the musculature of the ileum was contracted. In a short time, however, the spasm of the musculature disappeared. The ileum became moderately distended and it was then seen that the nodule could not be moved. By picking up the nodule between the thumb and the first finger the lesion could be seen as a purplish spot in the mucous membrane through the thin muscular coat stretched out over the lesion. This area was excised by removing an elliptic longitudinal

seemed most likely that this represented a large vessel which had become thrombosed with later organization and canalization. Another possibility was a small hemangioma present which bled into the tissue and this blood later became organized. Overlying this there was a small ulceration, the base of which was formed by one side of this organized hemorrhage, which was infiltrated near the surface with many acute inflammatory cells. No ulceration was seen in the other bit of tissue. No evidence of malignancy was seen.

On going over these sections carefully, however, we were convinced that this lesion represented a very small hemangioma of the mucous membrane in the ileum with ulceration of its surface. The patient's postoperative course was excellent immediately after operation. He had no further bleeding after operation. The next day, however, he developed a postoperative parotitis, which subsided under x-ray treatment but was complicated by a suppurative cervical lymphadenitis which required incision and drainage. He left the hospital on Feb. 21, 1943 and has had no further bleeding and is well.

Lesions of Small Intestine Producing Massive Hemorrhage with Symptoms Simulating Peptic Ulcer

section about 1 cm. in length, going through all layers of the intestine. Bloody fluid, with several clots, was removed by suction from the lumen of the intestine. The lesion was revealed as a small elevation in the mucous membrane with a central ulceration about 2 mm. in diameter. Shreds of blood clot were attached to the base of the ulcer. Following the removal of the lesion the longitudinally placed incision was sewed up transversely. The only other operative findings that might be considered abnormal were. 1. There was a small purplish point seen in the small intestine a few inches above the first nodule. This also was removed. It was not ulcerated, however, and on section looked like a small lymphoid follicle. 2. The lymph glands in the mesentery of the ileum were moderately enlarged but soft. It was not felt that they were definitely pathologic, and probably this moderate hypertrophy was only due to the absorption of blood from the intestine.

In each of two microscopic sections (fig. 4) there was moderate evidence of acute and chronic inflammation in the submucosa and muscularis. In several of the recuts there was a small mass of fibrous tissue which on further sections seemed to be continuous with a fairly large blood vessel without good vessel wall, which was filled with a thrombus, most of which had undergone organization and recanalization. Many small capillaries and vessels were present in this region. It

This young man's episode was mainly one of gross melena with some pains four or five weeks before admission. Because he had been under mental strain, the most likely cause was thought to be peptic ulcer with hemorrhage resulting in rapid passage of blood through the intestine. However, the gastrointestinal series was negative and repeated episodes of passage of partially red and partially tarry stools pointed away from the duodenum and to the small intestine as the cause of bleeding. The lesions in the small intestine considered were Meckel's diverticulum with peptic ulceration or some other type of small intestinal ulceration. The lesion found suggested a hemangioma. This case was managed correctly, and surgery appeared to have prevented a mortality.

COMMENT

Our primary purpose in this paper is not to discuss the differential diagnosis of massive melena in the presence of pain or to describe the various symptoms that may occur in small intestinal lesions but to emphasize the fact that lesions of the jejunum or ileum may mimic bleeding peptic ulcers.

The table summarizes our 3 cases as well as 6 other cases reported in the literature that had been diagnosed as bleeding peptic ulcer and proved to have been lesions of the jejunum or ileum as the cause of these symptoms (i. e. massive melena and postprandial pains). We wish again to stress the combination of these two symptoms, not the one or the other alone. In 6 of these cases there were roentgenologic changes in the duodenal cap which further abetted the tendency to diagnose such situations as bleeding peptic ulcers and closed the consideration of causes other than duodenal ulcer.

These 9 cases had various lesions responsible for this syndrome. There were 2 cases of benign leiomyoma, 2 of Meckel's diverticulum, 2 of hemangioma, 1 each of carcinoid, benign neurofibroma and carcinoma. We feel that other types of pathologic changes in the jejunum or ileum may cause this syndrome. However, the lesions here described are the only ones we have encountered either in the literature or in our own experience.

The importance of differentiating lesions in the small intestine from a gastric or duodenal ulcer as a cause of these symptoms is obvious. The question of immediate or eventual surgery is so different in these two types of diseases that we must avail ourselves of all possible diagnostic procedures. The use of a barium meal during active hemorrhage is not contraindicated, provided the roentgenologist is aware of the situation and does not use palpation. Case 3 in our series demonstrates the importance of the barium meal in helping to rule out the stomach and duodenum as the cause of the symptoms. After such a negative roentgenologic examination a Levine tube can be passed safely. The absence of blood in the gastric contents will help to eliminate the stomach or duodenum as a source of the bleeding.

As a result of the analysis of our cases and of those occurring in the literature, the following suggestions have shaped themselves to help differentiate lesions of the jejunum and ileum from gastroduodenal ulcers as the cause of this combination of symptoms:

1. One should be aware that small intestinal lesions may produce this syndrome.
2. The pains present are not quite as typical as those of peptic ulcer.
3. Hematemesis is usually not present.
4. The gastrointestinal series is negative for a definite ulcer, although it may be suggestive of duodenal irritability or pyloric spasm.
5. The roentgenologic study of the small intestine may occasionally show a defect, a widened loop or retained barium.
6. A Levine tube passed during the episode of melena will not reveal gross blood. (This is done after the barium meal has ruled out a gastric or esophageal lesion.)
7. A gastric analysis may show low values for hydrochloric acid.
8. The presence of a palpable mass which slides away from the fingers may suggest a lesion of the small intestine.
9. Small intestinal lesions may be present in addition to a peptic ulcer.²

CONCLUSIONS

The possibility of a small intestinal lesion should be considered in any patient who has repeated or continuous melena in the absence of hematemesis and in

whom the pains seem somewhat atypical for peptic ulcer. Such patients should have diagnostic studies even during the active phase to help determine whether the bleeding is from the common source, peptic ulcer, or from the uncommon origin in the small intestine.

ABSTRACT OF DISCUSSION

DR. THOMAS E. JONES, Cleveland: I am sure that many of us have had cases of so-called unknown causes of gastrointestinal hemorrhage. They are unknown because they are not fully investigated by exploratory laparotomy. I have had many cases in the past six months that might be worthy of report. A child aged 2½ years had multiple exsanguinating hemorrhages for the past year. Gastrointestinal examination was negative by x-ray. On account of my past experience with these, I advised exploratory operation. This revealed a Meckel's diverticulum with ulceration and containing typical gastric mucosa. A child aged 5½ years had multiple exsanguinating hemorrhages from the age of 7 months. Repeated examinations were negative. Always the advice given was "Well, the child may outgrow it." Examination again was negative. I advised exploratory operation and this time found a reduplication of the small intestine. This was over a length of about 8 inches in the midileum. One side of this reduplication contained normal ileal mucosa. The opposite half contained typical duodenal and gastric mucosa which was ulcerated and bleeding. A man aged 27 with multiple hemorrhages for the past seventeen years had gastrointestinal symptoms diagnosed as duodenal ulcer, and even though the x-rays were negative he was always treated for a bleeding ulcer, which was considered the most likely diagnosis. X-rays again were negative. At operation 2 feet below the ligament of Treitz was an ulcerating leiomyoma 1 inch in diameter. This was the cause of that man's trouble for the past seventeen years. These lesions in the small intestine are difficult to demonstrate by x-ray examination. The literature is full of reports of exploratory laparotomies which have been done and nothing found for these so-called "unknown" causes; however, a review of them will show that the exploration generally is made through an upper right rectus incision, the stomach and duodenum are inspected and, if negative, the hand is placed in the abdomen and the remainder of the abdomen is palpated blindly. Obviously, many small lesions will be missed. If one is going to do an exploratory operation one must visualize and palpate every bit of the gastrointestinal tract from the esophagus down to the rectum. I would make a plea for early exploratory operation in all these cases of exsanguinating hemorrhage, even though the x-ray is constantly negative.

DR. STOCKTON KIMBALL, Buffalo: I want to corroborate Dr. Segal's findings and mention 1 patient recently observed who was of interest because he was discharged from the Army with a diagnosis of duodenal ulcer. He had some indefinite symptoms and a severe hemorrhage while in the Army. I had had, according to his report, three x-ray examinations, none of which showed any lesion. He came into our hospital with severe hemorrhage, all rectal, with no hematemesis. His stool wasn't tarry; it wasn't bright red; it was the color of ripe sweet cherries. X-rays during the active bleeding showed normal stomach and duodenum. Operation showed a Meckel's diverticulum. Meckel's diverticulum is less unusual than the lesions reported by Dr. Segal and his associates but is of interest in relation to the fact that this man was discharged from the Army on the basis of bleeding ulcer, which he did not have.

Arabic Medicine.—The Arabians alone tended the lamp of the intellect in Europe during the Middle Ages. Filtered across the Pyrenees from Spain, Arabic culture was a stimulating force. The introduction of arithmetic alone was exciting. (Arabic numerals made possible addition, subtraction, multiplication, division, which cannot be done with Roman numerals the Arabs also introduced zero), but Islam's influence in medicine was deep and lasting.—Clendening, Logan: *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

RAPID DEVELOPMENT OF CARRIER
STATE AND DETECTION OF
POLIOMYELITIS VIRUSIN STOOL NINETEEN DAYS BEFORE ONSET
OF PARALYTIC DISEASE

GORDON C. BROWN, Sc.D.

THOMAS FRANCIS JR., M.D.

AND

HAROLD E. PEARSON, M.D.

ANN ARBOR, MICH.

Well established is the fact that the virus of poliomyelitis may be demonstrated in the stools of a high percentage of cases of the disease and that in some it may be present for varying lengths of time up to several weeks¹ and even months² after the onset of clinical disease. Virus has been recovered from the oropharynx in approximately 50 per cent of the cases when swabs or washings were obtained within a few days of the onset of paralysis,³ but its detection in this site is uncommon after the fifth day of disease.⁴

Presumptive evidence of the harboring of the virus for a considerable period prior to the onset of disease has been advanced by Francis and his associates,⁵ who described 5 cases of poliomyelitis with three deaths following tonsillectomy in children probably carrying the virus.

Taylor and Amoss⁶ demonstrated virus in nasopharyngeal washings from 2 children during a family epidemic, and in 1 of them it was present five days prior to the onset of the disease. Pearson,⁷ in a study of contacts of a case, isolated virus from the stool of a child who developed fever, coryza and diarrhea eleven days following the stool collection. This was apparently an abortive case ending with an uneventful recovery.

The present report relates the discovery of virus in the stool of a boy nineteen days prior to the onset of paralytic poliomyelitis.

EPIDEMIOLOGIC INVESTIGATION

The Detroit Recreation Camp is situated about 5 miles northeast of Brighton, Mich. It is owned and operated by the city of Detroit for the benefit of underprivileged boys and girls. The camp is situated in rather open country on a small lake. The boys' camp is on one side, while that for the girls is situated on the opposite shore. There is little or no intermingling of the two sexes, except occasionally at the

small cabin serving as a camp office at one end of the lake. The boys and girls swim at the same place but at different times of the day. The boys' camp consists of approximately ten cabins, a mess hall, common wash room, toilet and office. The cabins, in each of which are quartered 6 to 10 boys, including an older boy as counselor, are spaced in a row near the lake. Back of the cabins runs a road, on the other side of which are situated the common washroom, toilet, lake pump, septic tank, tennis courts and baseball diamond. The camp is clean, the toilet facilities are adequate and well taken care of. Screening is rather uniformly carried out. The dining room and kitchen are clean and well run. During the period of study the weather was hot and dry. Few flies or mosquitoes were seen or trapped.

On June 27, 1944 the camp opened its regular season and boys arrived from Detroit on that date. In one cabin, designated the Lincoln Lodge, were housed 10 boys, all between the ages of 13 and 17, who had had no previous association with one another. They were Joe K., Robert G., Ken M., Louis G., Edward L., Bob M., Dave W., Irving L., Rex M. and Richard W., the counselor. One of these, Rex M., went home on the second day of camp and another, Irving L., left July 5. Neither had been sick. Since the investigation was not undertaken until July 9, further consideration of these 2 was deemed unnecessary. Only Dave W., Robert G. and Richard W. of this group remained at camp after July 11.

Joe K. arrived at camp on June 27 and appeared normal and lively for the first day or two. On the morning of July 2 he went to church but was "mopy" later and complained of a stomach ache. He slept all afternoon. On July 3 he was apathetic but still attempted to participate in games. In the evening he was admitted to the camp infirmary with abdominal pain, headache and fever. On July 4 stiffness in the back and neck were apparent, as was pain in both thighs. He was admitted to Herman Kiefer Hospital on July 5 with the diagnosis of poliomyelitis. On August 28 weakness of both arms and paralysis of both legs were still present.

On July 9 the camp was visited and a study undertaken. In addition to 51 stools and 57 throat washings from the boys in other cabins, stool and blood specimens were obtained on 6 of the 7 boys who lived with Joe K. during his six day stay at camp, and throat washings were collected from 4 of the 7. All specimens were promptly frozen with solidified carbon dioxide.

Two of these contacts had been slightly ill on July 4, following a picnic hike. Edward L., who had been climbing actively, felt very thirsty and vomited. Later that day he complained of dizziness and a headache. The following day he still felt weak and his legs were stiff.

Bob M. complained of headache and fever but stated that he was prone to headaches. On July 5 his temperature was 100.8 F. and headache persisted. On July 6 he felt perfectly well.

Richard W. had been well until July 21, when he participated in a boat race, using his arms for paddles. That evening he thought that his arms were weak. There apparently was a very gradual progression of weakness in the upper extremities until July 28, when he was admitted to Herman Kiefer Hospital with a temperature of 100 F., pulse rate 88, respiratory rate 22. Lumbar puncture at that time showed 4 cells, all lymphocytes. The spinal fluid sugar was 80 mg. per hundred cubic centimeters and the total protein 64 mg. per hun-

dred cubic centimeters. The blood count showed 5,010,000 red blood cells, 100 per cent hemoglobin and 8,700 white blood cells, with 62 per cent polymorphonuclears, of which 54 per cent were filamented, 32 per cent lymphocytes and 6 per cent monocytes. On examination the neck showed moderate rigidity and the reflexes were hyperactive. The hands and arms were weak. He was given hot packs and physical therapy and on July 29 showed involvement of the right deltoid, right flexors of the fingers and extensors of the wrist. Weakness of the left arm had disappeared and there was improvement in the right shoulder girdle. On August 15 he was transferred to another hospital for further physical therapy. Throat washings and serum were obtained on July 29 and again a week later on August 7.

LABORATORY FINDINGS

(a) *Methods*.—Five of the 6 stool specimens from the boys in Lincoln Lodge were processed in the following manner: Five to 10 Gm. of stool was ground in a mortar with alundum and suspended in saline solution to make a concentration of 10 per cent. Low speed centrifugation was employed to clear the coarse particles, which were saved for intranasal inoculation. Ether to make 20 per cent by volume was added to the supernatant, and the specimens were shaken for one-half hour daily for six days. After exhaustion of the ether the material was centrifuged at 3,500 revolutions per minute for one-half hour and if bacteriologically sterile was retained for intraperitoneal inoculation. Usually 10 cc. of this material was recentrifuged in a small lusteroid tube at 3,500 revolutions per minute and used for intracerebral injection. All intraperitoneal and intracerebral specimens were adjusted to p_H 4.0 with hydrochloric acid before inoculation.

Rhesus monkeys were inoculated intracerebrally with 0.5 cc.; they were then given 10 cc. intraperitoneally and 2 cc. intranasally on the third day, another 0.5 cc. intracerebrally on the sixth day, and 10 cc. intraperitoneally and 2 cc. intranasally on the seventh or eighth day and again on the eleventh or twelfth day. Temperatures were taken at least once daily on all test animals.

The sixth stool specimen, Edward L., was made into a 10 per cent suspension in saline solution and given intranasally daily in 2 cc. quantities for ten days as suggested by Howe and Bodian.⁸

The throat washings were shaken for one-half hour on seven consecutive days with an excess of ether and after evaporation of the ether were inoculated in the same manner as the stool specimens except for the fact that the smaller quantities did not permit as many intraperitoneal inoculations.

(b) *Results*.—The specimen from Robert G. when inoculated into a rhesus monkey caused partial paralysis of the left leg and an extension tremor followed by definite weakness of the right leg. The diagnosis of poliomyelitis was confirmed by microscopic examination, which showed perivascular cuffing and leukocytic infiltration in both motor cortex and thalamus, infiltration of the pons and medulla, and pronounced cuffing, infiltration, neuronophagia and neuronolysis in the cervical, thoracic and lumbar regions of the spinal cord.

The monkey inoculated with the specimen of stool from David W. showed complete paralysis of both legs

in twelve days. The monkey receiving the stool specimen from Louis G. showed complete paralysis of both legs after fourteen days. In both instances microscopic examination revealed definite changes typical of poliomyelitis.

Two monkeys were inoculated intranasally with the Edward L. specimen. Both showed temperatures ranging from 104 to 106 F. and persisting for about ten days, shortly followed in one by moderate weakness of both arms and partial paralysis of the left leg. Microscopic sections showed extensive perivascular cuffing and leukocytic infiltration in the thalamus and to a moderate degree in the cortex and medulla, and extensive neuronophagia, neuronolysis, cuffing and infiltration in all levels of the cord, especially in the cervical region. The second monkey showed no paralysis but was killed, and microscopic examination revealed only slight perivascular cuffing in the cortex and no changes in the cord.

No virus was recovered from the stool specimen of Bob M.

No virus could be recovered from the throat washings of Robert G., David W., Bob M. or Ken M.

Inoculations of monkey 861 with a preparation of the stool specimen obtained from Richard W. on July 9 were begun on Nov. 13, 1944. Nine days later, on November 22, weakness of the animal's left arm was observed. This progressed, accompanied by ataxia. Weakness of the left leg was apparent on November 28. Further paralysis of the limbs did not develop, and by December 4 the monkey showed signs of improvement. It was killed, and microscopic examination revealed traces of leukocytic infiltration in the pons and some neuronophagia and neuronolysis in the medulla and the cervical region of the spinal cord. A suspension of the cord and medulla was inoculated into monkey 887 on December 7. This animal showed no rise of temperature or symptoms until December 23, sixteen days later, when it was apathetic and the hair ruffled. It was found dead in the cage the following morning and an autopsy was held. Microscopic examination showed typical changes characteristic of poliomyelitis, including perivascular cuffing and infiltration of the motor cortex, infiltration of the pons, cuffing in the thalamus and moderate neuronophagia and neuronolysis in both the cervical and the lumbar cord. Cytolysis was pronounced in the latter area.

Another suspension was made from the cord and medulla of monkey 861 and inoculated into monkey 899. This monkey showed no symptoms and was discarded after six weeks' observation.

The original stool specimen, which had been maintained in the frozen state, was again prepared for inoculation, and injection of monkey 896 started on Jan. 17, 1945. Nine days later, on January 25, the animal showed definite weakness of the left arm, was irritable and ataxic. It was killed January 29 and on section showed definite perivascular cuffing and infiltration of the motor cortex and moderate neuronophagia and cytotoxicity of neurons in the cervical cord. The cord and medulla of this monkey were passed to monkey 927, which remained well.

The two preparations from the original human stool had been retained in the ice box at 4 C. since Oct. 16, 1944 and Jan. 4, 1945 respectively. They were inoculated into monkeys 911 and 912 on February 7. Although both animals showed temperature elevations to 104 F., no other symptoms were apparent. They were killed two weeks after the temperature rise, and

⁸ Howe, H. A., and Bodian, D.: The Efficiency of Intranasal Inoculation as a Means of Recovering Poliomyelitis Virus from Stools, *Am. J. Hyg.* 40: 224, 1944.

microscopic examination revealed no changes characteristic of poliomyelitis.

Unfortunately no throat washings were obtained from Richard W. at the time of stool collection July 9, 1944, but fever and other symptoms were produced in monkey 898, which received washings taken on July 29, the day after the patient's admission to the hospital. The sections showed lesions typical of poliomyelitis. No virus was detected in throat washings collected one week later, August 7.

Monkeys were also inoculated individually with stools collected on July 9 from 10 boys 11 or 12 years of age in the nearest occupied cabin, two doors away, and from 2 boys who worked as "kitchen helpers." In none of these animals was evidence of illness observed.

COMMENT

An unusual opportunity has presented itself to determine not only the interval between exposure and the appearance of poliomyelitis virus in the stools of contacts but also to confirm the fact that virus may be present in the intestinal tract for some time before the onset of paralytic disease.

The probable interpretation of the results is that Joe K. arrived at camp in the incubatory stage of paralytic poliomyelitis, since the onset of his illness was five days after arrival. The occupants of the cabin had been brought together on June 27 for the first time; they were associated with Joe K. from that date until July 3. It is extremely doubtful that the brief illness of the two boys Edward L. and Bob M. on July 4 represented abortive poliomyelitis, since the incubation period would have been less than seven days. In addition, the stool of Bob M. was the only one from which virus was not recovered.

The recovery of poliomyelitis virus from the stools of 5 of 6 cabin mates collected on July 9 indicates that these boys had acquired the virus in the period of at most six days during which they were living with Joe K. This is supported by the negative tests for poliomyelitis virus in the stools of campers living in another cabin. It is apparent that multiplication of virus sufficient for the establishment of the intestinal carrier state is a very rapid process. Virus was not recovered from the throat washings of 2 of these boys at the time their stools were positive.

The second case of paralytic disease developed in 1 of the original 6 subjects nineteen days after collection of the stool specimen which was found to contain the virus. It is of interest to note that he was 1 of 3 from this group who remained at camp. No additional cases developed.

The detection of virus in this stool of Richard W. establishes the fact that virus may be present in the intestinal tract for some time before the onset of the paralytic disease. More than the usual precautions were taken to verify this finding. The original stool was processed twice and each time caused typical symptoms in monkeys. Diagnosis was corroborated by microscopic examination, which showed characteristic if not extensive involvement of the nervous tissue. In addition, passage of the cord and medulla invoked the disease, also verified by microscopic examination, in 1 of 3 monkeys. The fact that 4 other boys exposed for exactly the same period likewise had virus in their stools adds materially to the evaluation of the findings.

It is of interest that virus was recovered from the patient's throat washings on the day after hospitaliza-

tion but not from washings one week later. This is in close agreement with the findings of others.³ It may be that the presence of virus in the nasopharynx is associated only with the acute phase of the disease, while the intestinal tract is a potent source of virus before, during and for some time after the onset of clinically diagnosed poliomyelitis.

MERCURY POISONING IN TUNGSTEN-MOLYBDENUM ROD AND WIRE MANUFACTURING INDUSTRY

LIEUTENANT COMMANDER LEON LEWIS
MC-V(S), U.S.N.R.

In the United States at present there are five or six establishments which manufacture the bulk of tungsten, molybdenum and tungsten-molybdenum combinations used for electrical contacts and filaments in the great and diversified electrical and radio industries of the nation. In addition to these special plants the large electrical manufacturing concerns have departments which process these metallic products and serve as auxiliary sources of supply. This industry is relatively young and, since the pure metals used in the fabrication of rod and wire are not apparently toxic, it has aroused but little interest from the standpoint of industrial health. However, the processing of tungsten and molybdenum involves the use of metallic mercury and introduces the hazard of exposure to the toxic vapors of that metal.

In order to appreciate the mechanism for development of mercurialism among workmen employed in this industry it is necessary to have some knowledge of metal treating methods used. The ultimate product—contact, filament, wire or rod—may be fabricated from pure tungsten, from pure molybdenum or from various mixtures of the two metals. Usually the tungsten is manufactured in the plant by derivation from sodium, potassium or calcium tungstate. The molybdenum is made from ammonium molybdate and molybdenum trioxide. This phase of the industry also involves exposure to toxic dusts and vapors, but the incidence of illness is low and that problem will not be elaborated on here. After the pure powdered metals are obtained and sieved the first process is one of mechanical compression into rods of various sizes from 16 to 24 inches long and $\frac{3}{8}$ to 1 inch in square cross section. Further processing depends on whether the product is intended for electrical contacts, filaments, radio tube heaters, electrodes, x-ray targets or other types of equipment. For all of these products, however, the rods must be heat treated in order that the metal may be worked hot and drawn. Since true amalgamation is not possible, close molecular aggregation is achieved by intense heat, which is produced by passage through the rods of a low voltage high amperage current in an atmosphere of hydrogen.

Heat treatment is carried out in a separate department which houses a series of treating bottles. The apparatus¹ consists of a stand with a flat top over which a metal bell (or bottle) resembling a spirometer

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

bell is supported and counterbalanced by weights. In the top of the stand there is a central depression which, when filled with metallic mercury, serves as an electrical contact, and, on the outer margin, a ring depression or groove into which the open end of the bell may be lowered. The groove is also filled with mercury to form a gas tight seal. Within the bell and supported on the stand there is an upright bracket with a clamp into which the upper pole of the rod is fastened. A spring clamp is attached to the lower pole and it in turn rests freely in the central cup of mercury. The mercury thus forms a contact for passage of electric current while providing a liquid medium for mobility of the lower electrode during shrinkage of the rod. After the rod is placed and contact is made the bell or "bottle" is lowered until its rim fits into the mercury filled groove. Hydrogen gas is then admitted to the sealed chamber displacing the air, current is allowed to flow through the rod and heat treatment proceeds for a length of time determined by the composition of the rod and its intended use. The high temperature causes cohesion of the metal particles, which, after cooling, leave a brittle rod which becomes malleable when heated and can thus be worked into wire.

The treating process just described introduces the hazard of mercurialism. Forging and swaging required for manufacture of the final product do not involve industrial health problems and will not be described in detail. The rods, which are rectangular in cross section, are forged into round cylinders of varying diameters by means of swaging. Rods of large cross section are heated in a hydrogen atmosphere and pushed through an automatic hammering apparatus called a swaging machine. Rods of smaller cross section are worked in a swaging machine, which is a combined gas furnace and automatic forge. While heated by an encircling gas flame the rod is hammered by radially arranged hammers until it is forged into smaller cylindrical shapes. The rods are then drawn to wire or cut in various lengths.

The amount of mercury used and the extent of health hazard in this industry depend on many variable factors, such as the number of treating bottles, devices for the prevention of spillage and collection of waste mercury, the experience and caution of the workmen, ventilation, composition of the floors and temperature of the workroom. However, it is well known that exposure to seemingly small or laboratory quantities of mercury may cause toxicity to workmen.² Chronic poisoning may not occur except after many years. The experience of the hatting industry illustrates how insidiously prolonged absorption of minute amounts of mercury may undermine health and cause invalidism or death.

Mercurialism was one of the earliest recognized industrial diseases. According to Neal³ mercury was known in India in 500 B. C., and mercury stomatitis from its medicinal use was described during the first century A. D. References to mercurialism were made by Paracelsus (1567) in "Of Miners' Consumption and Other Miners' Diseases."⁴ In 1713 Ramazzini⁵ quoted

the opinions of numerous authorities and lent his descriptive powers to vivid accounts of the symptoms of mercurialism, writing in the chapter on diseases of miners "But it is from mercury mines that there issues the most cruel bane of all that deal death and destruction to Miners. Fallopio in his treatise 'Metals and other minerals' says that mercury miners can hold out for barely three years; Ettmüller in the chapter on mercury in his *Mineralogia* says that within four months they become subject to the palsy of the limbs (tremors), paralytic, and suffer from vertigo and this is caused by the mercurial spirits, which are particularly injurious to the nerves." Concerning gilders, Ramazzini says "We all know what terrible maladies are contracted from mercury by goldsmiths, especially by those employed in gilding silver and copper objects. This work cannot be done without the use of amalgam, and when they later drive off the mercury by fire they cannot avoid receiving the poisonous fumes into their mouths even though they turn away their faces. . . . Very few of them reach old age, and even when they do not die young their health is so terribly undermined they pray for death. Palsy of the neck and hands, loss of teeth, uncertain gait, and scelotyrbe, all these are assigned to them by Jüngken in his 'Experimental Chemistry.'" Olaus Borch is quoted from the "Medical Transactions of Copenhagen" regarding the case of a gilder stricken with mercurialism. "The distinguished author," say Ramazzini, "thinks that the palsy was caused by the impact on the nerves of the smallest possible atoms of steaming mercury (*corpuscula fumantis Mercuri minutissima*) and that directly these were taken into the blood mass they hindered its proper flow."

The uses of mercury have increased progressively during the era of industrialization and the hazard of mercurialism is no longer limited to the miner and the gilder. In their compilation of occupational hazards in 1933 Dublin and Vane⁶ listed eighty industries which use mercury in potentially harmful amounts. Among these industries are cinnabar mining and smelting, the fur felt and hatting trades (where the fortunate discovery of new carotting agents is eliminating the use of mercury nitrate in the treating of fur), the manufacture of Edison cell storage batteries, calibration of apparatus in the glass industry, manufacture of mercury fulminate in the explosives industry, reclaiming of precious metals from dental waste, installation of mercury boilers and vapor turbines, as well as many laboratory procedures in almost every conceivable field of science. So far as I know, however, there has been no prior report of mercury poisoning resulting from the manufacture of tungsten and molybdenum rod and wire.

In one of the large plants in which most of the following observations were made, the metal treating department was originally housed in an open shedlike structure and consisted of only three or four treating bottles. During several years of small scale operation no instances of mercurialism were observed and the hazard was not suspected. In 1938 the treating department was expanded and the apparatus was set up in a corner of the plant. The floor was wooden, no precaution was taken to collect spilled mercury, ventilation was poor and no attempt was made to provide fume hoods or forced draft. On Nov. 14, 1939 the first recognized case of mercurialism was referred for exami-

nation. Because of the symptomatology presented an inspection of the plant was undertaken and engineering consultation was requested. It was discovered that mercury was allowed to remain in puddles on the floor under the treating apparatus, that the metal had seeped through the floor and was dripping from the beams into a lavatory on a lower level and that in the use of the equipment no attempt was made to reduce the splashing of mercury droplets from the electrode cup or bottle seal. On occasions the waste mercury was swept up and discarded, but that which was in relatively inaccessible places was allowed to remain.

During the period from 1939 to 1944 a considerable number of cases of acute and chronic mercurialism were found among employees in the plant just described and in another somewhat smaller establishment. Only 2 clearcut cases were encountered from the smaller plant, both of which presented the typical findings of advanced chronic mercury poisoning (compare case 2) in workmen who had been continuously employed for seven years. The smaller plant exercised fair control and housed the treating bottles over a concrete floor in a large open room well ventilated by adjacent windows except during inclement weather. Even here, however, spillage was considerable and there was no provision for exhausting the treating equipment.

In order to diminish the obvious hazard in the plant where the first case of mercurialism was encountered, an engineering program was proposed. This was to have involved replacement of the wooden floor with metal plate, construction of a tilted single table top for all the treating bottles, which would prevent spillage and permit collection of waste mercury, housing of the apparatus within a closed hood, which would be forcibly exhausted and ventilated separately from the areaway from which the workmen were to control and load the treating equipment, and so on. This plan was modified to an extent which ultimately proved almost disastrous: the mercury saturated flooring was covered with a composition material, a few minor changes were made to collect spilled mercury, and the treating room which was closed off by partitions was air conditioned as a unit. Following the engineering foray the incidence of mercurialism rose sharply, for obvious reasons. The forced circulation of air throughout the department increased the vaporization of mercury, subjecting the workmen to an even greater exposure than existed before air conditioning the room. Concurrently the demand for increased production resulted in continuous operation for at least two and frequently three eight hour shifts daily.

Ultimately, many of the originally recommended protective measures were carried out, but despite installation of hoods and separate ventilation of the working area sporadic cases of mercurialism continued to occur. Morbidity was diminished by establishment of a medical program of preemployment examinations and periodic inspection, but the hazard of chronic mercurialism was effectually diminished only by the rapid labor turnover and the brief tenure of most of the employees. Improvements in the sanitary engineering of the plant were carried out during a period of rapid expansion and high productivity. As a consequence cases of mercurial stomatitis were found to occur within four weeks after employment, and 1 employee developed the condition after working in the department only a few days. In this instance a sheet metal worker installing

new exhaust apparatus had to cut through flooring impregnated with mercury and frequently swept up puddles of mercury with the sawdust and debris on the floor. On one occasion some mercury laden dust was accidentally swept directly into his face as he worked under the treating room floor. He presented a full blown gingivitis and associated systemic toxicity within a week after initial exposure.

The frequency of mercury poisoning in this industry is determined by a great many factors aside from the precautionary measures undertaken by the plants and the resulting degree of vapor concentration in the workroom atmosphere. When the production level is low, the incidence of mercurialism tends to fall. Similarly, when labor turnover is rapid there is little opportunity for development of subacute or chronic intoxication. However, the combination of failure of sanitary measures and high productivity has resulted in minor epidemics of acute intoxication, some of which have resulted in serious morbidity. One patient developed a spreading infection from suppurative gingivitis, which involved a preauricular lymph node and lighted up an old mastoiditis the spread of which extended to the auriculotemporal joint, the facial canal and parotid region. Cure was accomplished only after radical mastoidectomy, partial dental extraction, secondary incision and drainage and intensive local and parenteral administration of penicillin.

Case histories of chronic and subacute mercurialism are presented in order to illustrate the characteristic but variable symptomatology. The diagnosis is established when the clinical findings are correlated with a history of exposure, and it may be supported by the finding of mercury in the urine (in the absence of recent mercurial medication) or the demonstration of a toxic level of mercury in the occupational environment. Aside from the typical cases, problems involving difficult differential diagnoses were frequently encountered. One patient with gastrointestinal complaints, anorexia and vomiting was found to have trichinosis; another who complained of progressive weakness and loss of weight had pulmonary tuberculosis. One patient with questionable mercurial stomatitis had a demonstrable peptic ulcer. The importance of critical evaluation of symptoms and careful study of each case is emphasized because of the danger of assuming that every sick workman in an industry of known hazard is suffering from the effects of toxic exposure. In this particular field the finding of mercury in the excreta must not be permitted to mislead the diagnostician, since mercury is present in the urine of most of the subjects tested regardless of symptoms or the presence of intercurrent disease.

CASE 1.—Chronic mercurialism. A. B., a white man aged 25, on Oct. 28, 1941 reported for examination because of tremor of the hands, pain and numbness of the upper extremities and painful gums. He had been employed in the treating department for five months. He was not previously exposed to mercury and his industrial history was negative aside from employment as an anthracite miner for three years. The past history was noncontributory and the family history was negative. About a week prior to examination he noted soreness of his gums and for four days complained of slight headache. His appetite was poor. He had lost about 23 pounds (10 Kg.) during five months. Aside from loss of weight and anorexia there were no acute symptoms until Oct. 23, 1941, when the patient suddenly developed tremor of the hands while at work. It was necessary for another employee to help him place the

electrodes in the treating bottles because his hands shook so much that he was unable to carry on.

The patient on physical examination appeared asthenic. He weighed 129½ pounds (58.7 Kg.) and was 68¾ inches (175 cm.) tall. His best prior weight was 150 pounds (68 Kg.). The blood pressure was 116 systolic and 82 diastolic. The temperature and pulse were normal. He appeared somewhat undernourished and generally under par. There were many missing and several carious teeth. Dental occlusion was poor. The gums were hypertrophied and locally receded. A bluish line was present in the gum tissue about the upper and lower central teeth and in the upper left molar region. Pressure on the gum tissue caused bleeding and exudation from the gingival crevice. There were no significant findings referable to the neck, lungs, heart or abdomen. The genitalia and extremities were normal. Fluoroscopy revealed increased linear markings extending toward the apex from the right hilus.

There were no gross psychiatric abnormalities. Romberg's sign was negative. The gait was synergic and free, and there was no dysmetria or nystagmus. The sensory system was intact for all modalities. There was no disturbance of motor power, but coarse tremors were noted involving the outstretched fingers and the muscles of the upper extremities. There was a definite intention quality to the tremor, as indicated by the finger-to-nose and related tests. The handwriting showed a somewhat rhythmic irregularity of the script, particularly pronounced when attempting to write slowly. In the drawing of straight and curved lines irregular and progressive tremulousness was noted.

The cranial nerves were normal. The superficial reflexes exhausted readily. The deep reflexes were generally hyperactive, particularly those of the lower extremities. There were no pathologic reflexes.

The blood count was normal. There were 4.84 million erythrocytes. The hemoglobin (Sahli) was 13.8 Gm. and the leukocytes numbered 5,300. The differential count was normal and no stippling or other abnormality of the erythrocytes was observed. The sedimentation rate (Westergren) was 2 mm. per hour. The Kahn and Hinton tests were negative. The urinalysis revealed a specific gravity of 1.017, no albumin or sugar. The microscopic examination was negative. Examination of the urine for mercury by the dithizone method revealed a trace of the metal.

Dental consultation confirmed the diagnosis of mercurial gingivitis, although roentgenograms of the teeth failed to reveal much alveolar destruction. Under observation and treatment, which terminated on Nov. 19, 1941, there was progressive diminution of tremor, improvement of gingival tone and gain of weight.

CASE 2.—Chronic mercurialism. A. H., a white man aged 59, on Jan. 27, 1943 was hospitalized because of weakness, tremor and painful gums. He was employed in the treating department for approximately eight years, and worked continuously until Jan. 23, 1943. The plant where he was employed was ventilated only by means of windows situated behind the row of treating bottles, and during the winter the windows were opened only in mild weather. Early in 1942 the patient first noted soreness and dryness of the throat, and somewhat later he began to complain of periodic gastric distress. Ten months prior to examination he first became aware of tremor. His family physician was unable to find any physical abnormalities. Soreness of the mouth became progressively worse, but the diagnosis remained obscure. The past medical and family history were noncontributory. There was no history of alcoholism. The systemic review was negative.

On Feb. 10, 1943 physical examination revealed that the patient was well muscled, weighed 145 pounds (66 Kg.) and was 66 inches (168 cm.) tall. The blood pressure was 114 systolic and 76 diastolic. The temperature and pulse were normal. Both eyes showed immature cataracts. Hearing was slightly impaired. There were a few missing teeth. Dental occlusion was poor. There was moderate recession of the lower anterior gums and a faint gray line along the margin

of the receded tissue. The gums did not bleed easily on traumatization. The tonsils were of moderate size, not inflamed. The lung fields were clear. The cardiac examination was negative. The liver margin was palpable 1 fingerbreadth below the costal margin. The abdomen was otherwise normal. The genitalia and extremities were normal. The peripheral arteries were not unduly thickened.

The patient was of good intelligence and there were no psychiatric abnormalities except tension and anxiety. There was no disturbance of gait or station. There was a very noticeable intention tremor in the finger-to-nose test, and there were coarse tremors of the outstretched hands of intention type and of variable amplitude. During the course of observation and on attempted performance of purposive acts the tremor became much more pronounced and spread to involve almost all the muscles of the neck and trunk. There was no motor weakness. The cranial nerves were normal. The deep reflexes of the upper extremities were hypoactive, while those of the lower extremities were somewhat hyperactive. There was abortive clonus at the Achilles and patellar tendons. There was an equivocal Babinski reflex on the left and a positive Babinski reflex on the right.

The laboratory findings were essentially negative. There was no anemia. The leukocytes numbered 13,400 per cubic millimeter and there was a slight shift to the left. The sedimentation rate was 7 mm. per hour. The Kahn and Hinton reactions were negative. The blood sugar was 106 mg. per hundred cubic centimeters. Urinalysis revealed a specific gravity of 1.014, no albumin or sugar, and an occasional hyaline and coarse granular cast. Examination of the urine for mercury by the dithizone method gave a negative reaction. (At the time of examination the patient was hospitalized and had not been exposed to mercury for several weeks.)

The patient was reexamined on March 18, 1943, at which time he presented a similar but somewhat less pronounced tremor. There was no change in the physical findings. The handwriting at that time showed pronounced tremor, and the signature was illegible. In the drawing of straight and curved lines there was progressive and decided irregularity.

Another workman examined at the same time whose industrial exposure was identical also presented the characteristic neurologic findings of advanced mercurialism.

CASE 3.—Acute mercurial stomatitis. L. P., a man aged 42, Filipino, was referred for examination on Sept. 2, 1943 because of painful bleeding gums and excessive salivation. A musician until 1943, the patient was employed in the treating department for approximately six months. The family and past histories were negative except for gonorrhea in 1923. About two and one-half weeks prior to examination he first noted excessive salivation and a bad taste in the mouth. Subsequently his gums became painful and swollen and bled freely when the teeth were brushed. He informed the examiner that twenty-six metal treating bottles were in operation in the plant where he was employed and that twenty-four of them were in use continuously twenty-four hours daily.

Physical examination revealed that the patient was asthenic but well muscled. He weighed 112½ pounds (51 Kg.) and was 61¾ inches (157.5 cm.) tall. The blood pressure was 114 systolic and 66 diastolic. The temperature and pulse were normal. There was fetor oris. The teeth were in poor repair; many were missing and there were advanced caries, sordes and drifting of the remaining teeth. The gums were spongy and inflamed. There was a very faint dark discoloration along the gingival margin. In the submaxillary region there were tender enlarged lymph nodes. The neck was otherwise normal. The lungs were clear. The heart was negative to physical examination and fluoroscopy. The abdomen, genitalia and extremities were normal.

Neurologic examination was entirely negative. There was no disturbance of gait, station, coordination or sensory function. There were no tremors of the outstretched hands. Motor power

was normal. The cranial nerves were normal and the reflexes were physiologic.

A complete blood count was negative. There was no leukocytosis. The sedimentation rate was 26 mm. per hour (Westergren). The Kahn, Hinton and Mazzini tests were negative. The blood sugar (nonfasting) was 142 mg. per hundred cubic centimeters and the urea nitrogen was 11 mg. per hundred cubic centimeters. A smear from the gingival exudate revealed a large number of fusospirochetes and blood cells by dark field microscopy. The urine showed no mercury by the dithizone test. Routine urinalysis was negative. Roentgenograms of the mouth showed alveolar resorption.

The diagnosis was mercury poisoning, subacute, with mercurial gingivitis.

DIAGNOSIS

Mercury may enter the body as inhaled vapor, by ingestion of metallic particles or through the skin. Poisoning by the metal must not be confused with acute administration of mercurial salts, the effect of which is similar only in respect to the stomatitis which may develop during convalescence. Soluble mercurial salts are violent corrosive agents and are extremely nephrotoxic. Metallic mercury has neither of these properties, and renal disease is not characteristic of either acute or chronic mercurialism of industrial origin. Occupational mercurialism may develop acutely or subacutely following exposure to metallic mercury in a liquid or vapor state. More gradual exposure may result in chronic mercurialism without the development of signs of subacute intoxication. The clinical syndromes of acute and chronic mercurialism are fundamentally different, since the manifestations of the former are due to involvement of the gastrointestinal tract, while those of the latter are almost entirely of central nervous system origin.

Acute mercurialism may be suspected when there is a history of exposure to metallic mercury even in minute quantities and the patient presents an acute spongy gingivitis, an ulcerative stomatitis or, occasionally, colitis. The presence of a dark line on the gums is characteristic but not uniformly present. In differentiating the various types of stomatitis it is, of course, important to rule out recent administration of bismuth or of mercury and to exclude agranulocytosis and other diseases by routine laboratory tests. Lead poisoning is not usually a problem, since the blue gray line of plumbism is fairly distinctive and is not commonly associated with gingivitis. The presence of fusospirochetes must not confuse the issue, since these organisms commonly invade damaged gingival tissue and are present uniformly and in large numbers in mercurial stomatitis or gingivitis.

Aside from stomatitis the patient may complain of anorexia, weakness and digestive disorder. Ordinarily there are no tremors or other neurologic manifestations. Laboratory aids are of little help. The blood count is usually normal, although leukocytosis may result from the oral infection. If the urine is examined during or shortly after the period of exposure, metallic mercury will usually be found. It is essential that the test be done by an experienced toxicologist, and the method preferred is the test with dithizone.⁷ The presence of mercury in the urine is proof of exposure to mercury. It does not indicate whether mercury has been inhaled as a vapor or ingested as metal or salt and is not diagnostic of mercury poisoning.

Subacute mercurialism is usually suspected when workmen with known exposure present symptoms of general ill health. Usually the diagnosis is made by exclusion, and frequently in suspected cases nonindustrial disease is discovered. It is in this type of case that critical and thorough study is particularly necessary. The diagnosis is made when findings of chronic gingivitis, alveolar resorption and salivation are associated with anorexia, weight loss, asthenia and occasionally pallor, slight anemia and nervous irritability.

The most characteristic clinical syndrome is that resulting from prolonged exposure to very low concentrations of mercury. Chronic mercurialism is a disease of the nervous system and its manifestations are much the same whether the poisoning occurs among miners, hatters or metal treaters. The time required for development of the full blown syndrome varies with the exposure. The miner or smelter of cinnabar may come down with violent "shakes" within a year and at the same time may present a necrotic gingivitis. Usually it requires fifteen to thirty years' employment as a hatter to produce a similar syndrome, and signs of local mucosal disease may be entirely wanting. Tremor, known to all trades as the "shakes," is the most characteristic symptom. This tremor may be of variable intensity and there may be a constantly present fine component, but its most distinctive quality is that of intensification by attention or intention. It resembles the tremor of parkinsonism at times but differs in that the latter diminishes with intention while the mercurial tremor may evolve into sweepy jerky movements. It is much more pronounced than the intention tremor of disseminated sclerosis and is reinforced not only by intentional movements but also by the attention of the examiner, by emotional tension and by non-purposive acts. Early in the disease habitual actions may be performed by the involved extremity, but later even these are impaired by tremor. The tremor of chronic mercurialism can best be demonstrated even early in the disease by testing the ability of the workman to draw straight and curved lines and by observing the handwriting. It is important not only to study the results of these tests but to watch the actual performance. In some cases it is important to rule out malingering, especially since most cases involve the question of compensation. The tremor usually manifests itself as a progressive irregularity of line, sometimes violent at the end. The handwriting tends to become less legible, and frequently the subject will give up the attempt to write more than two or three words. Micrographia has been observed but is not characteristic.

In addition to tremor there are frequently complaints of muscle pain or tension. Right handed workmen usually suffer pain about the right shoulder, and the musculature of the region may be somewhat indurated and tender. Muscle cramps may occur, especially at night. Irritability, unexplained depression, even confusion may occur, but these signs of so-called mercurial erythism are not usually present except in advanced cases. Since most patients with advanced chronic mercurialism are middle aged or older, it is the rule to find associated systemic disease or manifestations of arteriosclerosis. Frequently it is impossible to determine whether the wide variety of symptoms is due to the intoxication or to coexisting somatic deterioration. There is no reliable basis for concluding that

⁷ Gtettler, A. O., and Lehman, R. A.: Simplified Procedure for Determination of Mercury, *Am. J. Clin. Path., Tech. Supp.* 2: 161 (Sept.) 1938.

mercurialism may aggravate arteriosclerosis, and frequently insuperable problems result when typical senile paralysis agitans develops in workmen long exposed to mercurialism. Since the problem is frequently medicolegal as well as medical, such issues are usually and properly resolved in favor of the disabled workman.

HYGIENE

In order to prevent toxic mercurial exposure in industry, the first requirement is a healthy respect for the dangerous properties of quicksilver. Since it is a liquid, mercury can seep into crevices, penetrate wooden floors, collect in interstices, mix with dust or amalgamate with solid metals. Wherever it collects, mercury vaporizes at room temperature and in the course of time potentially hazardous concentrations in the atmosphere may result from seemingly negligible spillage. Therefore, careful engineering and good housekeeping are the first essentials of plant hygiene. Whenever possible the metal should be used in closed procedures, and safety devices should be available in case of breakage or spillage. When used openly as in the heat treating of metals, the equipment should be so designed as to limit splash to a minimum, to insure collection of all droplets by an efficient gravity method and to avoid spaces and corners where puddles may accumulate. Ventilation is a difficult problem, and the error of forcibly ventilating open rooms containing mercury must be avoided. Exhausts should be placed so as to draw off the air from the apparatus where mercury is used, and the work space should be supplied with fresh air from an outside source. Wooden construction should be avoided, and flooring of concrete or composition materials should be maintained without cracks or open interstices. All apparatus should be simple in external construction and as far as possible free of needless angles or compartments. Isolating exposed mercury within exhaust hoods is to be recommended, provided the effectiveness of the exhaust system is frequently checked and the apparent safeguard is not allowed to contribute to carelessness. It is a common experience to find pools of mercury within hoods or on the floors after removal of guard plates.

According to Shepherd and his associates⁸ the toxic limit of mercury is 0.1 mg. per cubic meter of air. This is equivalent to approximately 1 part to 50,000,000 by volume. Apparatus is now available at low cost which is said to have a sensitivity of 0.082 mg. of mercury per cubic meter of air.⁹ Since there are not yet sufficient data to assure the safety of even 0.1 mg. per cubic meter over long periods of time, even more sensitive equipment may be desirable in order to check the effectiveness of engineering control. The General Electric instantaneous vapor detector¹⁰ is said to be sensitive to less than 1 part of mercury per billion by volume. In the use of the more sensitive instrument, however, caution must be exercised to exclude ozone and illuminating gas from the atmosphere tested, since similar effects to that of mercury are produced in the ultraviolet spectrum.

Aside from plant hygiene, close medical supervision of workmen and selective employment should form part of the control program. Preemployment examination

should screen out all candidates with chronic disease and dental abnormalities which might facilitate development of stomatitis. Radiography of the lungs should be routine. Dental examination should include radiography in doubtful cases, and all applicants with chronic gingivitis, deep gingival pockets, pronounced malocclusion and extensive uncorrected caries should be rejected. A general recheck should be made every month, and any workers showing evidence of swelling of the gums or complaining of sore mouth or salivation should be referred for dental examination. Neurologic examination should include tests for tremor, including a handwriting test. It is well to have a card with a faintly demarcated circle about 2 inches in diameter and crossed or angular lines about 3 inches long. The subject tested should be asked to trace the lines with uninterrupted strokes of the pencil and to write a standard test sentence dictated by the examiner. As far as chronic mercurialism is concerned, the handwriting test is the most valuable single means of early detection.

Personnel should be instructed in precautions necessary to prevent absorption of mercury. Facilities for washing and for showers after the work shift should be provided. Separate lockers should be provided for work clothes and for street clothes, and work clothes should be changed twice weekly. Clean lunch rooms should be provided, and food should not be permitted in the workrooms. Oral hygiene should be promoted and adequate dental care assured by periodic examination by the plant dentist.

TREATMENT

Acute industrial mercurialism is almost wholly a dental problem. In exceptional cases the systemic symptoms are sufficiently severe to warrant active medical care or even hospitalization. In such cases the judicious use of saline laxatives, high caloric soft diet and administration of sodium thiosulfate intravenously are usually the only measures required. Dental treatment should be directed to eradication of the associated fusospirochetal infection by means of any of the accepted agents. At times alveolar resorption may cause the loss of teeth. Complications arising from extension of infection may require chemotherapeutic or even extensive surgical measures.

Early chronic mercurialism frequently responds favorably to removal from exposure and ordinary medical supervision: sedation, nutritious diet, vitamin supplements, physical therapy. Sodium thiosulfate intravenously is a traditional remedy in mercurial and arsenical poisoning, but its effectiveness is difficult to evaluate and I have not been convinced of its usefulness.

Advanced involvement of the nervous system resulting in well established tremor, muscular tension and early psychologic change is extremely resistant to treatment in most cases. In some instances the symptoms subside spontaneously, but most of the time the tremor becomes fixed or progressive and a high degree of invalidism results. In the course of time many of these patients suffer total disability. In the group of cases referred to serious disability remained in the 2 advanced cases of nervous system disorder despite a long period of hospitalization and medical care.

SUMMARY

A specialized manufacturing industry is responsible for the supply of much of the tungsten, molybdenum and tungsten-molybdenum wire and rod used in the elec-

trical and radio industries. The process of heat treating these metal products involves the use of metallic mercury and introduces the occupational hazard of mercurialism.

Acute and chronic industrial mercurialism are not to be confused with acute poisoning by ingestion of mercurial salts. Acute industrial intoxication is largely a disease of the oral mucous membrane. Chronic mercurialism is a disease of the nervous system with characteristic manifestations and frequently unfavorable prognosis.

Sanitary engineering to prevent toxicity from mercury involves careful and controlled housekeeping, design of equipment to prevent accumulation of mercury and to promote collection of spillage, ventilation to insure a minimum concentration of mercury in the air and housing of apparatus within hoods which are forcibly exhausted. Supervised personal hygiene of workmen, preemployment examination and frequent medical observation are also essential for the prevention of morbidity.

In the treatment of mercurialism, removal from exposure is the first essential. Dental care is important in all cases showing gingivitis and stomatitis and is usually all that is required in early acute cases. The treatment of chronic mercurialism is largely empirical and consists of symptomatic and supportive measures.

Clinical Notes, Suggestions and New Instruments

SEDATION AS AN UNEXPECTED SYSTEMIC EFFECT OF PRIVINE

J. I. WARING, M.D., CHARLESTON, S. C.

Three cases are reported in which prinine hydrochloride produced sedation. This effect might not have been anticipated from the general character of the drug, which gives a complicated type of systemic stimulation in animals. Trial observations by Drs. F. M. Martin and R. P. Walton in the Department of Pharmacology disclosed that intravenous doses in 4 rats and 3 dogs produced hyperpnea, gross muscle spasms, occasional reflex hyperexcitability and convulsions. The effects of fatal doses suggestively resembled acute epinephrine deaths.

The clinical observations have a parallel in the systemic actions of ephedrine, which is ordinarily a stimulant or analeptic drug in adults. In a report by Bonzanigo¹ ephedrine was found to produce sedative effects frequently in children between the ages of 3 months and 14 years. Ephedrine was given to these patients in doses large enough to produce the characteristic hypertension.

CASE 1.—A girl aged 7 years, with vasomotor rhinitis, had been given a prescription (by another physician) which directed that 5 drops of prinine hydrochloride (0.1 per cent solution) be taken in each nostril three times a day. Consistently after each administration the patient felt drowsy and talked vaguely for several hours. After the drops were omitted she seemed normal.

CASE 2.—An infant girl aged 3 months with acute rhinitis was given a prescription for prinine hydrochloride (0.05 per cent solution) to be used as 2 drops in each nostril every four hours. After each treatment she slept for about eight hours, so that ordinarily the drug was given only at eight hour intervals. On one occasion she was definitely drowsy for twenty-

four hours after receiving only 2 drops of the solution. No similar effect was noted when another preparation (neosynephrin hydrochloride 0.25 per cent) was used.

CASE 3.—A boy aged 3 years drank an uncertain amount of prinine hydrochloride 0.05 per cent solution, probably 7 or 8 cc. He soon became quite drowsy and remained so for several hours afterward.

CURARE IN THE ACUTE STAGE OF POLIOMYELITIS

PRELIMINARY REPORT

NICHOLAS S. RANSOHOFF, M.D., LONG BRANCH, N. J.

A preparation of curare¹ has been used in the Orthopedic Service of the Monmouth Memorial Hospital in the past 4 consecutive cases of acute anterior poliomyelitis. In view of the present prevalence of this disease and the striking improvement of the symptoms obtained, the publication of the present preliminary report seems warranted.

REPORT OF CASES

CASE 1.—D. G., a girl aged 2½ years, was admitted with acute anterior poliomyelitis. Nuchal rigidity was pronounced, and there were rigidity of the entire back, hamstring spasm on both sides and gastrocnemius spasm on the right. The patient was treated in the routine way for ten days and was then given 0.9 mg. of curare per kilogram. Within two hours after the initial administration of the drug the child was sitting up in bed and playing for the first time. There was definite diminution of the nuchal rigidity and in the rigidity of the back. Both legs could be flexed at the hip with the knee extended to 90 degrees.

CASE 2.—M. G., a girl aged 13 years, was admitted to the hospital five days previously with the diagnosis of acute anterior poliomyelitis. She had been in almost continuous pain, which was not relieved by mild sedation or hot packs. There was complete paralysis of the left lower extremity, definite abdominal weakness and weakness of the right quadriceps. An intramuscular injection of 0.9 mg. of curare per kilogram was given. Within twenty minutes the patient was fast asleep for the first time since admission. She slept for ten hours, at which time she awoke complaining of pain in the back again. Hot packs were applied and after the first fifteen minute pack she dropped off to sleep again. The following day there was still a great deal of spasm of her back muscles and a great deal of rigidity of her back, although her nuchal rigidity had diminished considerably. Another dose of curare was administered, 0.9 mg. per kilogram. She has been pain free ever since. There was definite improvement in the strength of her abdominal muscles. Her back is still rigid, but much less so.

CASE 3.—J. D., a boy aged 10 years, was admitted with acute anterior poliomyelitis, ptosis of the left eyelid, paralysis of the right facial muscles, and difficulty in swallowing and breathing. There was pronounced nuchal rigidity and back spasm. The respirator was kept next to his bed with the idea that he might need it. After 0.9 mg. of curare per kilogram his breathing came easier and he swallowed without difficulty. The following day his ptosis had disappeared and there was much more strength in his facial muscles. On the second day he was found sitting up in bed.

CASE 4.—M. G., a girl aged 3, was admitted with acute anterior poliomyelitis. Nuchal rigidity and opisthotonos were pronounced. The child was crying continually and was most irritable. As by the time this child was admitted it had been decided to give curare to the patients with acute poliomyelitis, she was given immediately 0.9 mg. per kilogram. Within one-half hour her opisthotonos, which had kept her back off the bed, had disappeared and she was sleeping. The Kernig sign, which had been positive, disappeared.

From the Department of Pediatrics, Medical College of the State of South Carolina.

COMMENT

This preliminary report is being presented because there is a great deal of poliomyelitis in the country at the present time, and it is hoped that other observers will use this drug. Whether or not 0.9 mg. per kilogram is the ideal dosage is not known, but it is felt that in the more severe cases and in older children it will probably be necessary to increase this dose.

ACUTE SECONAL POISONING

REPORT OF A FATAL CASE WITH AUTOPSY

LIEUTENANT COMMANDER MARK C. WHELOCK (MC), U.S.N.R.
AND

CAPTAIN ALFRED M. FREEDMAN
MEDICAL CORPS, ARMY OF THE UNITED STATES

The wide and promiscuous use of barbiturates provides ample opportunity for their employment in suicides. Case reports of death due to most of the barbiturates have been made in the literature, and information is available concerning their toxicity.¹ A survey of the literature has failed to reveal any cases of seconal poisoning which terminated fatally. It was therefore felt important to report a case of seconal poisoning which eventuated in death.

REPORT OF CASE

A white man aged 24, a corporal, was discovered dead the morning of April 20, 1944, in his barracks. It was known that he had been a retiring and seclusive individual, who seemed to have made a poor adjustment to military activity. Recently he had been rejected for overseas duty because of "neurasthenia." He was not known to have had any other illnesses, and a survey of this and previous posts showed that he did not report on sick call or receive medical treatment at any time. On April 19 the victim behaved in his customary manner. He did not complain of any illness or appear unusually moody. He retired at the usual hour (10 p. m.), and during the night men sleeping in adjacent beds detected no disturbances or outcry.

The following morning, when his sergeant attempted to awaken him, he was found to be dead. Careful search of his effects, barracks and the surrounding area failed to reveal any drugs or poisons. No history of having obtained any drugs from army physicians, civilian physicians or local drug stores could be procured. A check of the careful record that is kept of all sedatives and narcotics, according to army regulations, failed to reveal any instances of drugs having been stolen.

Autopsy was performed on April 20, soon after death. Complete and careful autopsy, including the head, failed to reveal any anatomic cause of death. The positive anatomic findings were as follows:

Cardiovascular System: Hypertrophy of heart, 350 Gm., fatty infiltration of myocardium.

Respiratory System: Passive hyperemia of lungs, moderate; primary tuberculous focus, right upper lobe, obsolete.

Spleen and Hemopoietic Tissues: Passive hyperemia of spleen, moderate; acute hyperplasia of spleen, 440 Gm.; delayed clotting of blood.

Gastrointestinal System: Lymphocytic infiltration and dilatation of veins in the submucosa at junction of esophagus and stomach.

Liver: Parenchymatous degeneration of liver, 1,750 Gm.

Genitourinary System: Passive hyperemia of kidneys, moderate; adrenal rest, left kidney.

Bones and Joints: Hyperplasia of bone marrow.

Because of suspicion of possible drug poisoning, the stomach contents, intestinal contents, urine and blood were saved and submitted to the Army Medical School for toxicologic analysis.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

I. Hamburger, W. E.: The Promiscuous Use of the Barbiturates: II. Analysis of Hospital Data, *J. A. M. A.* 114: 2015 (May 18) 1940.

ysis. The study of the entire gastric content, 27 cc., revealed 0.9 Gm. of seconal. In 800 cc. of urine, 24 mg. of seconal was likewise found. No barbiturate was found in the blood. No evidence of any other drugs was found.

COMMENT

Seconal sodium is a short acting barbiturate that has been introduced for medical use in the past decade. The average adult hypnotic dose of seconal is stated to be 0.1 to 0.2 Gm.² In animal experiments, after oral administration of a single anesthetic dose, anesthesia appears within one-half hour and symptoms completely disappear in twelve hours. Clinically, seconal sodium exerts its effect within fifteen to twenty minutes, while its duration of action is between five and seven hours. Since seconal is a short acting drug, it is destroyed almost completely in the liver. Renal excretion occurs rather slowly and takes place only when a relatively high blood level is present. Seconal is not recovered in the urine when the dose is in the sedative range.³

In this case it is apparent that unconsciousness had existed for a considerable period before death occurred. The stomach was practically empty (27 cc. of stomach content) and the bladder was much distended (800 cc. of urine content in the bladder). It was estimated that death occurred at 4 to 5 a. m. or six to seven hours after the patient was observed to retire. The presence of 24 mg. of seconal in the 800 cc. of urine points to a high seconal level in the blood at one time. Likewise the discovery of 0.9 Gm. of seconal in 27 cc. of gastric contents indicates that a much larger dose must have originally been taken. It has been stated that fifteen times the ordinary hypnotic dose is fatal. The presence of a dose of seconal in the stomach almost as high as the fatal dose after six to seven hours of absorption had taken place brings one to the conclusion that the victim ingested a large amount of seconal. The failure to discover any seconal in the blood is explained on the basis of rapid destruction by the liver.

Early death in barbiturate poisoning is usually the result of paralysis of the respiratory center. The shorter acting barbiturates are particularly prone to produce death by respiratory depression.² The conclusion reached in this case shows that the cause of death was acute seconal poisoning.

The findings were submitted for review to the Army Medical Museum, and the interpretations were confirmed. Further, the case was also submitted to Dr. Alan R. Moritz, professor of legal medicine, Harvard University, who likewise agreed with the diagnosis of acute seconal poisoning.

This death due to an overdose of seconal is believed to be the first one reported. Noble⁴ reports that a woman recovered following the ingestion of 28½ grains (1.9 Gm.) of seconal, although she was in deep coma for a considerable period of time. The patient treated by France, Barnett and Yonkman⁵ was found at the point of death one hour after consuming 125 grains (8.3 Gm.) of a mixture of soluble pentobarbital and seconal. Vigorous treatment with picrotoxin and metrazol brought about full recovery. An unsuccessful suicide attempt has been described by Dorsey.⁶ The victim took 20 grains (1.5 Gm.) of seconal and was found nine hours later comatose, breathing so slowly that artificial respiration was necessary. Heroic therapy with picrotoxin was successful. The amount of seconal ingested in the case reported here is, of course, unknown, but has been estimated as at least 45 grains (3 Gm.).

This case emphasizes that the same care must be used in the employment of this drug as with other barbiturates. Further, it illustrates the necessity for saving stomach and intestinal contents, urine, blood and tissue, as needed, in order to pursue toxicologic investigation in all cases of death in which the cause is not readily apparent.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The following statement has been authorized for publication by the Council on Pharmacy and Chemistry.

AUSTIN SMITH, M.D., *Secretary,*

THE ADDITION OF SALT TO DRINKING WATER

A number of preparations containing sodium chloride have been made available commercially for distribution during hot weather to office employees, industrial workers and others. Some of the products are simple tablets containing sodium chloride, others have enteric coating to permit passage of the material into the intestine before disintegration occurs, and still others contain additional substances such as minerals and vitamins. All are intended to provide sodium chloride and other factors to combat the harmful effects of excessive heat, exercise and sweating.

The need for the addition of vitamins, salts other than sodium chloride and minerals to salt tablets does not have sufficient evidence to justify their routine use until more satisfactory evidence is provided. They can therefore be dismissed from the casual prescribing practice.

However, there is strong evidence to support the administration of additional amounts of sodium chloride to the diet of those subject to strenuous exercise and excessive perspiration. Normally a person leading a sedentary life does not need salt in addition to the amount ordinarily placed in food. If copious sweating occurs, such an individual may require additional salt. Excessive perspiration is frequently encountered in those leading a strenuous physical life and may even occur during more moderate temperatures. However, such sweating entails loss of both water and salt, although the loss of salt varies with the amount of sweating and with conditions of acclimatization of the individual. Under special conditions man may become acclimated to hot weather, and work has shown that individuals exposed continuously to hot weather excrete less salt in their urine, compensating thereby for the loss of salt by sweat.

Sweat contains from 0.2 to 0.3 per cent, perhaps even up to 0.5 per cent, of sodium chloride. If a person perspires profusely considerable salt will be lost; for example, an individual might lose from 10 to 15 Gm. of salt. A man performing heavy work may lose a quart of sweat per hour. At the same time the chlorides in the blood decrease, and even though water is drunk it is not retained in the body and the body becomes dehydrated. Drinking too much water in the presence of dehydration created by loss of salt in water can cause water intoxication.

Under ordinary conditions the appetite or hunger for salt regulates the intake. A simple criterion used by many to judge the amount of salt needed is the amount of water drunk and excreted per day. When the total water intake is under 1 gallon per day the amount of salt in the usual normal diet (about 16 Gm.) is claimed to be adequate to cover salt losses by sweating, but with water intake above 1 gallon usually more salt is needed. However, one Council consultant has found that in profuse sweating neither thirst nor salt hunger is a reliable guide. He and his associates found that rats and persons select salt and water so that a 0.6 per cent salt solution is ingested. The same investigator advocates drinking a 0.2 per cent salt solution when profuse sweating occurs, such as when a man performs heavy work. On the other hand, the man who performs light work probably needs no more salt than can be obtained in the ordinary diet. If additional amounts of salt are required they can be obtained by the use of well salted foods.

When Boulder Dam was being built, considerable enthusiasm was aroused concerning the supplying of additional amounts of salt, which compensated for the amount lost by

the body and at the same time caused the men to drink more water. Smelters, iron workers and others who work in the presence of great heat have apparently been successfully given salted water to prevent heat cramps.

Symptoms of heat exhaustion and heat cramps are commonly associated with a salt deficit. Frequently victims suffer from severe cramps, often localized in the abdomen, the condition apparently being brought on by drinking large amounts of water at a time when the loss of sodium chloride from the body is excessive. The condition can be treated at once by the intravenous injection of sodium chloride solution, but it can be prevented by maintaining an adequate salt intake with the water. So far as is known, no harmful effects follow the use of such salt water if it is properly prepared, although the use of salt in tablet form may irritate the stomach and cause nausea and vomiting and other disturbances in some persons. The amount of salt taken should be adjusted to actual need and, as is known, this need will vary with exercise and acclimatization. In areas where periods of hot weather are broken by cooler weather or where people are subjected to strenuous exercise only at periodic intervals, the need for salt supplement may exist only during these special periods, and this need may become less after the people become acclimatized. There is such great variance among different individuals according to their physiologic adjustments that it seems best to provide these persons with a 0.1 to 0.2 per cent drinking water solution when a need for extra salt seems indicated. Some may easily be satisfied merely by the addition of salt to their food. A 0.1 per cent solution may be made by dissolving about 1 Gm. of sodium chloride in each quart of water, or about 1 Gm. per liter.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., *Secretary.*

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT STRAINED PEARS AND PINEAPPLE, consists of Bartlett pears, pineapple, sugar and water.

Analysis (submitted by manufacturer).—Total solids 16.72%, moisture (by difference) 83.28%, ash 0.22%, fat (ether extract) 0.31%, protein (N \times 6.25) 0.34%, crude fiber 1.10%, carbohydrates other than crude fiber (by difference) 14.75%, calcium (as Ca) 0.014%, phosphorus (as P) 0.009%, iron total 0.54 mg. per hundred grams, iron "available" (bipyridyl method) 0.55 mg. per hundred grams, copper (McFarlane method) 0.15 mg. per hundred grams.

Calories.—18 per ounce; 63 per hundred grams.

Vitamins.—Vitamin A equivalent...26 U. S. P. units per hundred grams
Thiamine0.24 mg. per hundred grams
Ascorbic acid0.2 mg. per hundred grams
Riboflavin0.017 mg. per hundred grams
Niacin0.33 mg. per hundred grams

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT STRAINED PEARS, consists of pears, sugar and water.

Analysis (submitted by manufacturer).—Total solids 13.54%, moisture (by difference) 86.46%, ash 0.20%, fat (ether extract) 0.37%, protein (N \times 6.25) 0.31%, crude fiber 1.02%, carbohydrates other than crude fiber (by difference) 11.64%, calcium (as Ca) 0.016%, phosphorus (as P) 0.009%, iron total 0.44 mg. per hundred grams, iron "available" (bipyridyl method) 0.33 mg. per hundred grams, copper (McFarlane method) 0.23 mg. per hundred grams.

SATURDAY, SEPTEMBER 8, 1945

DEFICIENCY OF B VITAMINS IN MAN

A recent report of Keys and his associates¹ recounts their observations in an extensive investigation of the influence of a borderline deficiency and of an acute deprivation of some of the B group of vitamins in human subjects. Eight normal young men were given a diet providing a daily allowance of 3,300 calories, 75 Gm. of protein and 0.18 mg. of thiamine, 0.25 mg. of riboflavin, 3.5 mg. of niacin per thousand calories, with 5,000 units of vitamin A and adequate vitamin D. Four were given in addition 1 mg. of thiamine, 1 mg. of riboflavin and 10 mg. of nicotinic acid amide; these served as the supplemented control group. The experiment extended over one hundred and sixty-one days.

The urinary excretion of thiamine in both groups declined rapidly and in less than thirty days reached a more or less constant level. At the end of the study 1.1 per cent of the intake of thiamine of the restricted group appeared in the urine, whereas 8.5 per cent of that of the supplemented group was excreted through the kidneys. With respect to the loss of riboflavin in the urine, the value for the restricted group was 12.1 per cent and that of the control group 22.5 per cent. Many tests were made on physical fitness, psychomotor function, basal metabolic rate, cardiac function, emptying time of the stomach, glucose tolerance, sensory and intellectual functions and personality evaluations; differences in the response of the two groups were not found on the basis of the foregoing evaluation or with respect to clinical ophthalmic or neuropsychiatric examinations. Only on the basis of the resting level of pyruvic acid in the blood was a difference detected; there was a slight but statistically significant increase in this value in the restricted group.

The study on acute deficiency followed immediately and continued for twenty-three days. Two previously restricted subjects continued on a diet containing negligible amounts of the three B vitamins concerned but otherwise adequate, and 2 were given the same food

but with 1.5 mg. of thiamine, 1.5 mg. of riboflavin and 25 mg. of niacin per thousand calories; 2 previously supplemented subjects were given the deficient ration and two the same diet plus the added B vitamins. The most obvious change was seen in the restricted-deficient pair, who showed increasing anorexia from the seventh to the twenty-first day; similar, though somewhat delayed, signs were observed in the 2 men who had been in the supplemented group and now were on the deficient diet. Changes in the results of the objective tests were "surprisingly small . . . in view of the marked changes in general behavior and obvious signs of subjective distress." There were no changes in the tissues which are looked on as likely to furnish early signs of vitamin deficiencies, but again there were slight increases in the lactic and pyruvic acid levels of the blood toward the end of the test period. Deterioration in endurance and coordination was progressive, but there were few if any effects on strength, vision, hearing and speed.

The evidence indicates that thiamine is the limiting factor in these experiments. It appears that, though there was little deviation from the normal as a result of the restriction of thiamine, superimposition of acute deficiency indicates that the allowances in the first part of the study were less than adequate. From a practical point of view there still exists the need for more incisive tests for detecting incipient deficiency of the B vitamins, especially thiamine.

ALCOHOL PROBLEMS

In a report to its lay members the Research Council on Problems of Alcohol presents a summary of studies carried on during the period of 1939 to 1944.¹ A critical survey of the literature to 1941 on the effects of alcohol on the individual was completed by the New York University College of Medicine group headed by Norman Jolliffe and E. M. Jellinek. Volume I of this study (Yale University Press, 1942) is devoted to the etiology and treatment of abnormal drinking and to the mental and bodily disorders of chronic alcoholism. Workers at the Phipps Psychiatric Clinic of Johns Hopkins University under Dr. Curt P. Richter investigated the question of the appetite shown by animals and human beings for alcohol and whether this appetite gives any indication regarding the nutritional needs fulfilled by alcohol. When rats were given free access to purified minerals, vitamins, carbohydrates, fats and proteins, in separate containers, they made dietary selections which kept them in good health. For example, adrenalectomized rats ingested large amounts of sodium chloride and thereby kept themselves alive and free from symptoms of insufficiency; parathyroidectomized rats ingested large amounts of calcium solutions and

1. Keys, A.; Henschel, A.; Taylor, H. L.; Mickelson, O., and Brezel, J.: *Am. J. Physiol.* 144: 5 (June) 1945.

1. The Research Council on Problems of Alcohol, 60 East 42d Street, New York 17: Report on Studies 1939-1944: A Summary for Lay Members.

avoided phosphorus solutions, thereby keeping themselves alive and free from tetany; pancreatectomized rats ate large amounts of fat and avoided carbohydrate, thus helping to eliminate their symptoms of diabetes. This knowledge of the rat's ability to make advantageous dietary selections was utilized as a tool for the investigation of nutritional problems. The problems, according to these authors, were literally put to the rat, and the rat with its selections has usually given a definite answer. It was found that rats prefer alcohol to water in concentrations of 1 to 6 per cent. Under normal conditions they take only small amounts of alcohol in higher concentrations. By their preferences the rats placed alcohol in the group of substances which have nutritional value. When forced to take larger amounts of alcohol, rats reduced their food intake almost directly in proportion to the caloric intake obtained from the alcohol. Since the rats grew and thrived under these circumstances, the results indicated that alcohol may replace large amounts of food. Of primary importance is the fact that the total caloric intake did not surpass its normal level. Taste threshold and maximum preference concentrations were determined for 240 human subjects between the ages of 4 and 50 years. The taste thresholds were similar to those found in rats. The preference concentrations varied through a much wider range. While most children and adults did not like alcohol in concentrations above 15 per cent, about 8 per cent liked the alcohol up to and including 50 per cent. The investigators suggest that these youngsters who liked alcohol in such high concentrations might be the potential drinkers, while the others who disliked it, even in low concentrations, might thus, by their taste mechanisms, be kept from drinking larger amounts of alcohol.

Studies on the toxic factors in alcoholism were conducted by the New York State Psychiatric Institute. Studies of the nervous system in a series of rats which had been intoxicated with ethyl alcohol and reared with various diets, each diet deficient in a single vitamin of the B group, with the exception of nicotinic acid, revealed pathologic alterations characteristic of the deficiency of the corresponding vitamin; the addition of alcohol produced neither qualitative nor quantitative modifications of the pathologic picture. Studies of the central nervous system in a series of guinea pigs treated with alcohol and kept deficient in vitamin C did not show significant pathologic changes.

Drs. Lloyd H. Ziegler and Josef A. Kindwall studied the conditioned reflex treatment of 29 patients. Of the 29, 16 were considered successes and 13 failures. Although this is a preliminary study on a small number of persons, the authors are inclined to consider the conditioned reflex treatment a promising method of management of drunkards.

Surveys of facilities for the treatment of alcoholism revealed that hospital facilities for the care and treatment of alcoholic addicts in the United States are scanty and inadequate, and that those which exist are not always utilized to the best advantage. There has been little recognition of the need of diagnostic centers to determine the indications for therapy on an individual basis or of the need for facilities for adequate treatment. The authors feel that the diagnostic and therapeutic services, as well as research and professional education in this field, are functions of hospitals. Hospitals are best staffed and equipped to undertake the multiple phases of diagnosis and early medical treatment, particularly if the services of psychiatrists are available. Diagnostic clinics of the type established at Hartford and New Haven under the "Yale Plan" should prove of immense value as the first step toward securing the segregation of various types of patients.

In a study on the role of alcohol in the development of liver cirrhosis, Jolliffe indicates that the frequency of this condition is greater in the inebriate portion than in the temperate and abstinent part of the population but that it would be fallacious to assume from this fact alone that alcohol bears a direct causal relationship to cirrhosis. The attempts of numerous investigators to produce cirrhosis in animals by the experimental administration of alcohol have been uniformly unsuccessful. Jolliffe and Jellinek have computed the participation of inebriety in deaths from liver cirrhosis to be approximately 35 per cent. Thus, about 65 per cent of deaths from liver cirrhosis occur in noninebriates. Recent clinical studies have demonstrated that several other afflictions of the inebriate are caused by dietary deficiencies rather than by the direct action of alcohol. Among these are polyneuropathy, pellagra, some cardiovascular disturbances, niacin deficiency and encephalopathy and Wernicke's encephalopathy. A study of 198 inebriates with liver cirrhosis has failed to demonstrate any beneficial effect of high carbohydrate diets or of vitamin B₁ on the course of cirrhosis of the liver in the inebriate.

The Council's research program for the future proposes to follow two major lines: First, the committee will suggest problems and plans for research on the cause or causes (biologic and social) of alcoholism in man. The committee will include the study of effects of alcohol on various organs, functional processes and capacities. The second aspect of the program provides for establishment in the hospitals of medical schools of one or more research centers with facilities for diagnosis and treatment. Through such studies it may be possible in time to recognize early in life, especially in adolescents, the organism personality with subnormal resistance to alcohol in the hope of providing an effective method of preventing alcoholism.

Current Comment

THE DISCHARGE OF ARMY MEDICAL OFFICERS

During the last week several letters have been received signed by groups of physicians in various Army Medical Corps installations throughout the country urging that a different plan be adopted for the release of medical officers from the Army. Some of these letters have insisted that the American Medical Association should conduct a determined campaign in behalf of the technic they propose. One letter just received from Sheppard Field, Texas, signed by sixty-one medical officers, proposes that

those civilian physicians below the age of 45 who have been taxing their strength by working as many as fourteen hours a day be allowed the privilege of serving their country during the remainder of the emergency. This would allow those physicians who have completed three or more years of service and/or those above the age of 38 an opportunity to return to their homes and their families. It should be noted that the eight hour day, as is common in the peacetime army, would be less taxing to their strength than the fourteen hour day, no matter what their physical status may be.

The letter further proposes that this utilization of civilian physicians be accomplished by joint action of the American Medical Association, the Procurement and Assignment Service and the Office of the Surgeon General. The American Medical Association officially or through any of its agencies has no authority or power to compel any action on the part of the Army authorities or the Office of the Surgeon General. THE JOURNAL hopes shortly to announce the revised system by which some thirteen thousand physicians of the Army medical department are to be released by the end of 1945 as stated in an announcement made last week by Surgeon General Kirk.

NONEXCRETION OF PENICILLIN IN BOVINE MILK

Bryan and his associates¹ have recently reported unsuccessful attempts to treat chronic streptococcic mastitis of cattle by intravenous injection of massive doses of penicillin. Seeley and his associates² of the Storrs Agricultural Experiment Station, Connecticut, made quantitative studies of the rate of excretion of intravenously injected penicillin into bovine milk. After the introduction of 500,000 Oxford units of a calcium salt of penicillin into the jugular vein of a Jersey heifer the animal was milked dry every half hour during the first six hour period and at hourly intervals thereafter, the final sample being taken twenty-four hours after the injection of penicillin. Preliminary tests had shown that, as measured by zone size milk enhances the in vitro action of penicillin against the

test organism. With the cup technic, a zone of inhibition was not observed with any of the milk samples drawn from the injected heifer. From these negative results Seeley concludes that the lactating bovine mammary gland is not permeable to penicillin.

LOCAL PROGRESS IN PUBLIC HEALTH

The 1944 annual report of the health department of the city of Racine¹ comes to hand coincidentally with the retirement of the city health officer after serving the city for almost fourteen years. His immediate predecessor served for over eight years. Both these health officials represented the same training, background and attitude toward public health work. Both worked in close cooperation with the local medical society and received the support of that society regularly. During these twenty-two years the city of Racine received six honor awards for outstanding health service in the Interchamber Health Conservation Contest sponsored by the American Public Health Association and the National Chamber of Commerce. Characteristic of the health service in Racine is an adequate budget in keeping with the budgets for other departments of the city government; the per capita appropriation for 1944 was \$1.23. In that year other notable records were achieved. Not a single birth was attended by a midwife; every birth was reported by a physician; only 11 of the 1,147 resident births were delivered at home. Only 2 mothers died in childbirth, a rate of 1.3 per thousand births. The infant death rate was 21.9 per thousand births and there was not a single death from diarrhea and enteritis in children under 2. The city suffered not a single death from acute communicable disease. There was not an outbreak of illness traceable to any food product. Extensive laboratory services in the public health field were offered to the local physicians. This notable health record is accentuated by the fact that never at any time has the city of Racine had outside funds or subsidies either from state, from federal or from private sources, except for a small state participation in venereal disease control work. Racine is an industrial city with large numbers of families in the moderate income classification. The report establishes the success that can be achieved by local control, local financing and local leadership. The two health officers who served the city for more than two decades were not in either instance residents of Racine. They were both Wisconsin men, and the political leadership which brought them to the city, supported their work and cooperated with them was definitely and at times militantly local. Vociferous demands for federal financing, leadership and control are thus answered by the record of this city, doubtless not unique. Local initiative, local financing and local control have been sufficient in Racine to assure good progress in public health.

MEDICINE AND THE WAR

ARMY

COMMISSIONS IN THE MEDICAL DEPARTMENT, REGULAR ARMY

1. The Surgeon General invites the attention of all Medical Department officers and former officers, other than those retired, of both male and female component corps, to War Department Circular 243, dated August 10, on the subject "Interest in Commissions in the Regular Army," a summary of which follows:

(a) "Present indications are that a number of outstanding officers who have proved their capabilities in this emergency will be needed in the Regular Army peacetime establishment. Until appropriate legislation is enacted, the War Department cannot announce the conditions which will govern selection of these officers or the number required. However, it is desired that officers who have served in the emergency, whether or not they are still on active duty, be given the opportunity of indicating their interest in obtaining a Regular Army commission. An officer making such a statement of interest may go off active duty or remain in the service without prejudice to his chances of being tendered a commission when legislation is enacted. It is the intention of the War Department that the fact that an officer has not remained in active service will not affect the grade to be offered or the position he will occupy on the promotion list.

(b) "The plan for selecting and integrating officers into the Regular Army officers corps, as well as the size and composition of that corps, will finally be determined by Congress. The War Department will recommend that these officers integrated into the Regular Army be of such age and physical condition as will permit them to serve for a reasonably long period before being retired. No officer will be appointed in a grade higher than that which he held in wartime.

(c) "The content of this circular will be brought to the attention of every officer at the earliest opportunity."

2. Officers currently on active military duty and who are interested in being considered for commission in the Regular Army, following enactment of appropriate legislation, may submit a statement of interest to their immediate commanding officer as outlined in the circular.

3. Officers and former officers other than those retired who have served since Dec. 7, 1941 and who have been relieved from active military duty under honorable conditions may submit their statement of interest as outlined in the circular direct to the Adjutant General, Washington 25, D. C.

4. The submission of a statement of interest in a Regular Army commission in no way obligates an officer to apply for such a commission at any time.

5. At such time when the policies establishing the conditions and procedures for selection and integration of officers into the Regular Army, Medical Department, are finalized, the Surgeon General will make immediate announcement in this publication.

ESTABLISH EIGHT CENTERS FOR TREATMENT OF TROPICAL SKIN DISEASE

Major Gen. Norman T. Kirk, Surgeon General of the Army, recently announced the establishment of eight centers specializing in the treatment of tropical skin disease. The centers will be devoted to the care of men returned from overseas, particularly the Pacific areas. The number of beds involved was not made public, as the program may be expanded or contracted as the need arises. The centers will be at Wakeman General Hospital, Camp Atterbury, Indiana; Brooke General Hospital, Fort Sam Houston, Texas; Madigan General Hospital, Fort Lewis, Wash.; Moore General Hospital, Swannanoa, N. C.; Harmon General Hospital, Longview, Texas, and in the U. S. Army General Hospitals at Camp Edwards, near Boston, Camp Butner, near Durham, N. C., and Camp Carson, near Colorado Springs.

ARMY AWARDS AND COMMENDATIONS

Major George A. Marks

The Legion of Merit was recently awarded to Major George A. Marks, formerly of Boston. The citation accompanying the award read "For exceptionally meritorious conduct in the performance of outstanding service in the Southwest Pacific Area from July 11, 1942 to June 13, 1944. Major Marks organized, trained and commanded a portable surgical hospital which was attached to an infantry regiment during the Papuan campaign. Under his exceptional leadership the unit moved in close proximity to front line troops and achieved a remarkable record in the care of the sick and wounded. It was essentially as a result of his professional ability and guidance that many lives were saved under the most difficult conditions of jungle warfare. Later, as a surgical consultant, he visited hospitals in advanced areas as an instructor and adviser. His knowledge and advice proved invaluable both in the treatment of casualties and in assisting and planning of additional facilities. By his outstanding ability in the field of surgery, Major Marks made a signal contribution to medical treatment in the Southwest Pacific Area." Dr. Marks graduated from Harvard Medical School, Boston, in 1928 and entered the service April 1, 1942.

Captain Richard O. Bagley

The Air Medal was recently awarded to Capt. Richard O. Bagley, formerly of San Francisco and now flight surgeon with the 51st Troop Carrier Squadron, based in Italy. The award was made for the part he played while the squadron was engaged in the evacuation of partisan wounded and Allied airmen who had evaded capture by the Germans from behind enemy lines in Yugoslavia. On one occasion Captain Bagley was flown at night in a C-47 troop carrier type aircraft without escort to an unfamiliar landing strip deep behind enemy lines in Yugoslavia to administer treatment to a seriously wounded and unconscious American air crewman. Through the treatment given by Captain Bagley at his destination, under the pressure of detection by the Germans at any time, and his continual treatment throughout the flight, the patient's condition was maintained until he was delivered to a base hospital in Italy. Dr. Bagley graduated from the University of Colorado School of Medicine, Denver, in 1939 and accepted a commission as 1st lieutenant in the Army Medical Corps in August 1942.

Lieutenant Colonel James W. Branch

The Bronze Star and Oak Leaf Cluster was recently awarded to Lieut. Col. James W. Branch, formerly of Hope, Ark., "for meritorious service in connection with military operations against an enemy of the United States in France, Belgium, Luxembourg and Germany during the period Dec. 1, 1944 to April 25, 1945. As surgeon of the 6th Armored Division, Lieutenant Colonel Branch has exhibited unusual aggressiveness, courage and ability in supervising and coordinating the medical activities of the division. His humanitarian efforts have greatly facilitated the prompt treatment and evacuation of Allied prisoners of war and the immediate alleviation of suffering of displaced persons. The faithful cooperation and careful devotion to duty displayed by him have been of material benefit and reflects great credit on himself and the Medical Corps." Dr. Branch graduated from the University of Arkansas School of Medicine, Little Rock, in 1935 and entered the service Feb. 3, 1941.

Captain Grover R. Fattic Jr.

Capt. Grover R. Fattic Jr., formerly of Hot Springs, Mont., was recently cited "for meritorious achievement in connection with military operations against the enemy on Luzon, Philippine Islands, from Feb. 1, 1945 to May 10, 1945. Captain Fattic did under the most trying difficulties of weather and enemy shell fire personally supervise all phases of the evacua-

tion of the wounded by litter and ambulance throughout the period. His cool determination, excellent judgment in the commanding and training of Medical Department soldiers, and the efficient evacuation and excellent treatment of the sick and wounded reflect great credit on him and on the military forces." Dr. Fattic graduated from the College of Medical Evangelists, Los Angeles, in 1938 and entered the service June 26, 1941.

Captain Jacob Thomas Farris

The Bronze Star, the Silver Star and the Purple Heart were awarded posthumously to Capt. Jacob Thomas Farris, formerly of Richmond, Ky. The citation accompanying the Bronze Star read "For meritorious service in connection with military operations against an enemy of the United States in — from June 6 to June 29, 1944." The Silver Star citation read "For gallantry in action against an enemy of the United States in —, July 25, 1944. The initiative and courage displayed by this officer reflects great credit on himself and the armed forces of the United States." Dr. Farris graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1940 and entered the service Aug. 26, 1941. He was killed by enemy fire in Normandy, France, near St. Lo, Aug. 3, 1944.

Colonel J. Guy Strohm

The Legion of Honor (officer) and the Croix de Guerre (with palm) was recently awarded to Col. J. Guy Strohm, formerly of Portland, Ore., for "his splendid work in command of the American Forty-Sixth General Hospital while this unit was supporting the First French Army." Dr. Strohm also shares in the Meritorious Service Unit Plaque awarded the American Forty-Sixth General Hospital some time ago and also the Legion of Honor (chevalier) and the Croix de Guerre (with star) for meritorious service as division surgeon of the Ninety-First Division during the first world war. Dr. Strohm graduated from Rush Medical College, Chicago, in 1910 and entered the service June 15, 1942.

Brigadier General Charles C. Hillman

Brig. Gen. Charles C. Hillman, Washington, D. C., was recently awarded the Legion of Merit for "service from August 1939 to August 1944. As chief of the Professional Service, Office of the Surgeon General, by his untiring effort and devotion to duty, he was responsible for the development of this service from a small prewar division to a large, well balanced organization. Under his direction physical standards were set up for the wartime army and professional direction was given to the blood plasma program and many other technical procedures which have been highly successful in the war effort." General Hillman graduated from Rush Medical College, Chicago, in 1911.

Colonel Charles C. Hubbard

The Bronze Star was recently awarded to Col. Charles C. Hubbard, formerly of Uniontown, Pa., for the part he played in the campaign to liberate the southern Philippines as chief of the Plans and Operations Division of the Medical Section, where, according to the citation, "he was largely responsible for the adequate medical service and evacuation which was available at all times for every sick and wounded individual in each of the Eighth Army operations." Dr. Hubbard graduated from Jefferson Medical College of Philadelphia in 1930 and entered the service in July 1941.

Major Joseph Robert Campbell

Major Joseph R. Campbell, formerly of the Mayo Foundation, Rochester, Minn., was awarded the Bronze Star recently and an oak leaf cluster to the Bronze Star. Both citations read, in part, "for meritorious and direct support of combat operations." Dr. Campbell is division psychiatrist for the 3d Infantry Division in Germany. He graduated from the University of Manitoba Faculty of Medicine, Edmonton, Alberta, in 1937 and entered the service Aug. 21, 1942.

Captain Jackson C. Neavles

Capt. Jackson C. Neavles, formerly of Webster Groves, Mo., was recently awarded the Bronze Star for meritorious service in action with his army airborne division in Holland. He also

served as a battalion surgeon with his unit during the Normandy campaign. Dr. Neavles graduated from Washington University School of Medicine, St. Louis, in 1942 and entered the service April 25, 1943.

Captain Charles H. Burnett

Capt. Charles H. Burnett, formerly of Boston, was recently awarded the Bronze Star for meritorious achievements in connection with military operations in the Mediterranean Theater of Operations. Describing Captain Burnett's work from Feb. 11, 1944 to May 8, 1945 the citation pointed out that "by virtue of his zeal and scientific skill he carried out during this period field studies of blood and blood substitutes which were of outstanding value in promoting the correct usage of these agents in the treatment of the seriously wounded. His untiring efforts and devotion to duty reflect great credit on himself and on the Medical Corps of the Army of the United States." Dr. Burnett graduated from the University of Colorado School of Medicine, Denver, in 1937 and entered the service Aug. 22, 1942.

Colonel Earle Standlee

The Cross of Knight Commander, Order of the Crown of Italy, was recently awarded to Col. Earle Standlee, formerly of Washington, D. C., in recognition of his meritorious services in Italy during the war. Dr. Standlee graduated from Baylor University College of Medicine, Dallas, in 1925 and entered the service June 1, 1925.

Lieutenant Colonel Luke A. Mulligan

Lieut. Col. Luke A. Mulligan, formerly of Leonia, N. J., as commanding officer of the 16th Field Hospital received for his unit the Meritorious Service Unit Plaque for exceptional service during the period from Dec. 21, 1944 to March 9, 1945. The 16th Field Hospital went to the aid of those in Bastogne and Avanches. Dr. Mulligan graduated from Long Island College of Medicine, Brooklyn, in 1929 and entered the service July 26, 1942.

Captain Charles H. Hall Jr.

The Bronze Star was recently awarded to Capt. Charles H. Hall Jr., formerly of Brooklyn, for meritorious services in support of combat operations in Italy. Captain Hall's medical detachment took part in the engagements of Africa, Salerno, Volturno River, Cassino, Anzio Beach, Rome, Florence and the Gothic line. He graduated from Long Island College of Medicine, Brooklyn, in 1939.

Major Merrill B. Rubinow

Major Merrill B. Rubinow, formerly of Manchester, Conn., was recently awarded the Bronze Star for heroic action on the Western front. His unit, the 37th Medical Battalion of the Third Army, was the recipient of a Meritorious Service Unit Citation. Dr. Rubinow graduated from Long Island College of Medicine, Brooklyn, in 1942 and entered the service Sept. 12, 1943.

Colonel Martin E. Griffin

The Cross of Knight Commander, Order of the Crown of Italy, was recently awarded to Col. Martin E. Griffin, formerly of Washington, D. C., in recognition of his meritorious service during the Italian campaign. Dr. Griffin graduated from the State University of Iowa College of Medicine, Iowa City, in 1925 and entered the service June 1, 1925.

Lieutenant Colonel Joseph O. Boydstone

The Bronze Star and Purple Heart were recently awarded to Lieut. Col. Joseph O. Boydstone, formerly of Little Rock, Ark., during the campaign of the division in France, Belgium, Luxembourg and Germany. Dr. Boydstone graduated from the University of Arkansas School of Medicine, Little Rock, in 1932 and entered the service Sept. 20, 1940.

Captain Regis F. Asselin

Capt. Regis F. Asselin, formerly of Detroit, was recently awarded the Bronze Star for distinguished and meritorious service, over and beyond the call of duty, in accomplishing malaria control in a highly malarial area. Dr. Asselin graduated from the Long Island College of Medicine, Brooklyn, in 1939 and entered the service Sept. 5, 1942.

NAVY

TRANSFER OF RESERVE MEDICAL
OFFICERS TO THE REGULAR
UNITED STATES NAVY

New and notable opportunities for outstanding medical careers in the Navy have now been developed. Reserve medical officers who have given thought to the matter of transferring to the Medical Corps of the regular Navy should have full information about the opportunities and inducements warranting such a move.

The Medical Corps of the Navy must be greatly enlarged to provide for postwar officer requirements, and applications for transfer of reserve officers are invited and urged.

The development of the residency-type graduate training program in United States Naval Hospitals, described again in THE JOURNAL September 1, is of importance to medical officers in all age groups interested in specialization.

The American College of Surgeons has recently surveyed and officially approved thirty-two United States naval hospitals for graduate training in various of the surgical specialties.

The Council on Medical Education and Hospitals of the American Medical Association, acting jointly with the American boards, has surveyed and approved for residency training in medical and surgical specialties three of these hospitals and at this moment is engaged in a similar survey of thirty-seven additional naval hospitals for the same purpose.

Officers in the older age groups already trained and classified as specialists will fit into key positions in the educational program as teachers and leaders as well as clinicians. Younger officers, when assigned for duty in these naval hospitals, and also in many instances in unsurveyed and unclassified activities, will be in a position to train and perfect themselves in the specialty of their choice and to have credit for the time so spent applied toward applications for American board certification and fellowship in the American College of Surgeons or the American College of Physicians, as well as later election to national special societies.

In other words, a medical career in the Navy now affords opportunities for training, for attainments and for clinical and teaching activities as well as for honors quite comparable to those of civilian practice and limited only by an individual's initiative and ability.

Every medical officer has been classified and graded in the Professional Qualification Section of Personnel Division, Bureau of Medicine and Surgery, together with a listing of any expressed preferences for special training or experience. This will expedite all matters of appropriate assignment and proper utilization of officers in peacetime activities.

It is the intention of the Bureau of Medicine and Surgery to make every effort to assign reserve medical officers transferring

to the Medical Corps of the Navy to postgraduate instruction in naval hospitals at the earliest practicable date consistent with the exigencies of the service.

The bureau intends also to resume extensively the use of the civilian medical centers for postgraduate training of medical officers of the Navy.

It is reemphasized that the Navy is in need of a large number of additional medical officers in the Medical Corps of the regular Navy and that interested reserve officers desiring further information on the subject, or wishing to make application for transfer, should communicate accordingly with their commanding officers at the earliest possible moment.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Lewis D. Norris

Lieut. Lewis D. Norris, formerly of Minneapolis, was recently awarded the Bronze Star. The citation accompanying the award read "For meritorious achievement in connection with operations against the enemy on Iwo Jima, Volcano Islands, from Feb. 24 to March 16, 1945. Throughout the active phase of the operations Lieutenant (junior grade) Norris, as battalion surgeon with a Marine Division, displayed outstanding professional skill, sound judgment and courage in the care of our own and enemy wounded. All sick and wounded prisoners of war captured within the division's zone of action were brought into the aid station of his battalion. Because of his untiring initiative, devoted courage and skilful professional ability he was a constant inspiration to his men and contributed materially to the success of the operation. His conduct was in keeping with the highest traditions of the United States Naval Service." Dr. Norris graduated from the State University of Iowa College of Medicine in 1943 and entered the service April 8, 1944.

Lieutenant Commander George J. Miller

Lieut. Comdr. George J. Miller, formerly of Hempstead, N. Y., was awarded the Silver Star by Lieut. Gen. H. M. Smith for "conspicuous gallantry and intrepidity while acting as battalion surgeon of a marine artillery battalion in action against the Japanese on Saipan in the Marianas Islands in the summer of 1944." With complete disregard for his own safety and without shelter, Commander Miller gave medical treatment and supervised the evacuation of 275 casualties from his battalion and adjacent units. Dr. Miller graduated from the Long Island College of Medicine, Brooklyn, in 1940 and entered the service July 25, 1941.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Letterman General Hospital, San Francisco: Surgery of the Hand, Dr. Edmond Dana Butler, September 15; Diagnosis and Treatment of Diabetes Mellitus and Diabetic Coma, Dr. H. Clare Shepardson, September 29.

Station Hospital, Camp Stoneman, Pittsburg: Diagnosis and Treatment of Various Skin Diseases, Dr. John Graves, September 29.

Hammond General Hospital, Modesto: Thoracic Surgery, Dr. Brodie Stephens, September 19.

U. S. Naval Hospital, Mare Island: Subacute Bacterial Endocarditis: Diagnosis and Treatment with Penicillin, Dr. Henry D. Brainerd, September 14.

Station Hospital, Fort Ord: Early Ambulation of Surgical Patients, Dr. H. Glenn Bell, September 29.

UNRRA LAUNCHES ANTIMALARIA
PROGRAM IN GREECE

As part of an all out drive against the critical increase of malaria in Greece, the largest air borne antimalaria program yet launched in Europe will soon be undertaken by UNRRA in Greece in cooperation with the Greek government. Roy F. Hendrickson, acting director general of UNRRA, stated that ten specially equipped planes are being sent to that country to be used in spraying mosquito breeding areas with DDT. According to the UNRRA chief medical officer in Greece, Dr. J. Balfour Kirk, there are some areas in the country where 100 per cent of the population is infected with malaria fever. Data now available indicate that 40 to 50 per cent of the country will be infected during the season which lasts from April through October. The present number of victims approaches the three million mark. Prior to the war the estimated average number of cases in Greece was approximately 50,000 per year. In addition to the planes and other equipment necessary for the treatment of malaria swamps, UNRRA will aid Greek health officials in the work of spraying 750,000 homes with DDT.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Sept. 3, 1945.

Formation of Committee to Assist Veterans Seeking Medical Careers

District of Columbia medical and nursing school heads have formed a committee under Dr. Paul F. Dickens, District chairman of the WMC Procurement and Assignment division, to assist veterans seeking to study medicine, pharmacy, dentistry, nursing and allied science. The committee includes Dr. Walter A. Bloedorn, dean of George Washington University School of Medicine; Father David V. McCauley, dean of Georgetown School of Medicine; Dr. John W. Lawlah, dean of Howard University College of Medicine; Dr. John P. Burke, dean of Georgetown University School of Dentistry; Dr. Roger M. Choisser, head of George Washington University School of Medical Technicians; Sister Marie Gerarda, superintendent of nurses at Georgetown University Hospital; Mrs. Helen Shoemaker, nurses' superintendent at Sibley Memorial Hospital, and Lloyd W. Hazelton, executive officer of George Washington School of Pharmacy.

The Army expects to release 13,000 doctors by the end of 1945 and the Navy 8,200 by September 1946, officials of both services have told the House Military Affairs Committee. Surgeon General Kirk also revealed that the Army will discharge 3,500 of its 15,000 dentists and 25,000 of its 56,000 nurses by December. He stated that the Army has 45,000 doctors for its 400,000 patients in army hospitals throughout the world.

The Navy plans to cut its present 3,389,000 strength to 500,000 enlisted men by September 1946 and will reduce its medical staff from 14,000 to 5,800 by that time, stated Capt. H. G. Hopwood, special assistant chief of naval personnel. In the next three months the Navy will release 1,000 nurses and 1,000 doctors. The Navy will shortly change its point discharge system.

Former WAC Staff Director Reports to General Bradley

Onetime executive secretary to the medical director of the Veterans Administration for twelve years, and for ten years an attorney in the solicitor's office, Lieut. Col. Mary Agnes Brown, former WAC staff director in the Pacific, has reported to Gen. Omar N. Bradley, Administrator of Veterans' Affairs, to serve as an adviser on matters pertaining to women veterans. More than 300,000 women are either serving or are already released from the armed forces. Brig. Gen. Frank T. Hines, who has been named American ambassador to Panama, was honored at a reception in the Mayflower Hotel, given by Edward B. Scheiberling, national commander of the American Legion.

Enrollment of Servicemen in Medical Schools

Despite the efforts of the War Manpower Commission to encourage veterans to enroll in medical and dental schools, the Army and Navy have enrolled more than 1,000 servicemen as first year medical students. This action is said to have been taken because of commitments to the schools and to the men. The services will probably keep them in school for only one semester. The Navy announced that, although its V-12 program will be liquidated starting November 1, 1,500 V-12 students are entering medical and dental schools for one year. The majority are enrolled in medicine. The Army has 400 enrolling in medical schools this fall under the Army Specialized Training Program. Some 5,700 other medical and 1,450 dental students in the Navy V-12 program will remain on active duty until the end of the semester now current or starting before November 1. An Army spokesman said that the Army was

obligated under the act setting up the Specialized Training Program to continue it until Congress calls a halt. Veteran meantime, complain that they have been told they cannot go into medical school under the G. I. bill for a year or more because schools are full. A representative of the War Manpower Commission Procurement and Assignment board estimates that 75 to 80 per cent of medical schools are occupied by Army and Navy students. Ten days ago the WMC announced plans "to enroll immediately 12,000 students for medical, dental, premedical and pre-dental courses beginning this fall from among veterans now being discharged from the armed forces." This recent check discloses that medical schools are filled and cannot take the large number of students the WMC said could be enrolled.

Plight of Disabled Veterans Being Studied

Government leaders are giving more and more thought to care for disabled war veterans, who will carry a double load in making their readjustment to civilian life. Those departments charged with work on behalf of such veterans are studying advanced methods of treatment and job finding. Business and government agencies, such as the Army Map Service and Bertram's Pipe Factory in Washington, are already making it a point of hiring disabled veterans. The public is also making a conscious effort to assist in their readjustment.

Army Medical Service May Be Transferred

The proposed reorganization of the War Department is said to include plans to take the Surgeon General's Office, along with the Adjutant General's Office and the Provost Marshal General's Office, out of the Army Service Forces and place them directly under the Secretary of War.

Committee on Scientific Exhibit

MEDICAL MOTION PICTURES

Medical motion pictures are available on a loan basis from the American Medical Association to medical societies, medical schools, hospitals and other scientific groups. Requests should be instituted as far in advance as possible, so that the proper reservations can be made. The exact shipping addresses and dates should be given at the time of the request. Responsibility for the projection and care of the film must be borne by the individual or organization which is borrowing it. The American Medical Association does not have projectors available for loan.

The only expense incurred is that of transportation both ways. However, careless handling resulting in serious damage may be charged to the borrower.

Requests should be sent to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

ANESTHESIA

Dynamics of Respiration (1938; revised 1944)

Silent. Color. 16 mm., 3 reels, 400 feet each.
Running time about 40 minutes.

Dynamics of respiration showing normal respiration, respiration at various stages of anesthesia and in different pathologic conditions. Prepared by the Departments of Anesthesia, Radiology and Photography, University of Wisconsin Medical School, Madison, for the Special Exhibit on Anesthesia of the American Medical Association.

Pediatric Anesthesia (1944)

Silent. Color. 16 mm., 2 reels, 400 feet each.
Running time 30 minutes.

For use in demonstrating the technique of anesthesia in children. Prepared by Dr. M. Digby Leigh, Department of Anesthesia, Children's Memorial Hospital, Montreal, Que., Canada.

Regional Anesthesia for Operations on the Neck (1938)

Silent 16 mm, 1 reel 400 feet
Running time about 16 minutes
Film shows detail of technic of anesthesia for operations on the neck
Prepared by Dr Ralph M Tovell, Section on Anesthesia, the Mayo Clinic, Rochester, Minn, for the Special Exhibit on Anesthesia of the American Medical Association

Signs of Inhalation Anesthesia (1938)

Silent 16 mm, 2 reels, 300 feet each
Running time about 25 minutes
Details of signs of inhalation anesthesia with charts presented by Dr Arthur E Guedel, Los Angeles
Prepared by Dr Henry S Ruth and Dr J Harvey Sigafos, Department of Anesthesia, Hahnemann Hospital, Philadelphia, for the Special Exhibit on Anesthesia of the American Medical Association

Technic of Blocking Sacral Nerve (1938)

Silent 16 mm, 1 reel, 400 feet
Running time about 15 minutes
Film shows details of technic for blocking sacral nerve
Prepared by the Section on Anesthesia, the Mayo Clinic, Rochester, Minn, for the Special Exhibit on Anesthesia of the American Medical Association

The Technic of Carbon Dioxide Absorption in Anesthetic Atmospheres (1938)

Silent 16 mm, 2 reels 400 feet each
Running time about 30 minutes
Details of technic for absorbing carbon dioxide in anesthetic atmospheres
Prepared by Departments of Anesthesia and Photography, University of Wisconsin Medical School, Madison, for the Special Exhibit on Anesthesia of the American Medical Association

The Role of Carbon Dioxide in Convulsions During Anesthesia (1942)

Silent 16 mm, 1 reel about 200 feet
Running time about 7 minutes
The picture shows convulsions during anesthesia and their control
Prepared by Departments of Anesthesia, Radiology and Photography, University of Wisconsin Medical School, Madison

PHYSICAL MEDICINE

Aids in Muscle Training (1938)

Silent 16 mm, 1 reel 300 feet
Running time about 12 minutes
Demonstration of sling suspension exercises for the upper and lower extremities graded exercises on a powdered board for the lower extremities and three kinds of "walkers" for reeducation exercises
Prepared by the Council on Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago

Contraction of Arteries and Arteriovenous Anastomoses (1935)

Silent 16 mm, 1 reel 250 feet
Running time 10 minutes
This film visualizes the contraction of arteries and arteriovenous anastomoses as seen through a glass chamber installed in a rabbit's ear
Prepared by Dr E R Clark, University of Pennsylvania School of Medicine, Philadelphia

Effects of Heat and Cold on the Circulation of the Blood (1933)

Silent 16 mm, 1 reel, 300 feet
Running time 12 minutes
Demonstration of the effect of heat and cold on circulation as seen through a glass chamber installed in a rabbit's ear
Prepared by Dr E R Clark, University of Pennsylvania School of Medicine, Philadelphia

Effects of Massage on the Circulation of the Blood (1933)

Silent 16 mm 1 reel 200 feet
Running time 8 minutes
Demonstration of the effect of massage on circulation as seen through a glass chamber installed in a rabbit's ear
Prepared by Dr E R Clark, University of Pennsylvania School of Medicine, Philadelphia

Massage (1938)

Silent 16 mm 1 reel 100 feet
Running time 4 minutes
Demonstration of technic of massage, describing the various movements and why they are performed in a given way
Prepared by the Council on Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago

Occupational Therapy (1938)

Silent 16 mm 2 reels 450 feet
Running time 12 minutes
This film demonstrates occupations that may be prescribed by physicians to motivate and control the desired physical or mental activity of the patient and assist in his adjustment to long hospitalization
A section on cerebral palsy is included, picturing indirect muscle training through prescribed activity and stressing the importance of early treatment to prevent growth of faulty habit patterns
Prepared by the Council on Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago

Underwater Therapy (1938)

Silent 16 mm, 1 reel 400 feet
Running time about 16 minutes
Presentation of therapeutic use of large and small exercise pools, Hubbard tanks and home made tanks, and demonstration of types of exercises given in cases such as infantile paralysis, cerebral palsy and postoperative congenital dislocation of the hip
Prepared by the Council on Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago

OTHER SUBJECTS

Angina Pectoris (1942)

Sound Color 16 mm 2 reels 1,600 feet each
Running time about 1½ hours
A Summary of Objective Studies (Part I Clinical Characteristics Part II Physiology Part III Pathology Part IV Treatment)
Produced by Dr Joseph E F Riseman, Boston

Back to Normal (1945)

Sound 16 mm, 1 reel, 550 feet
Running time about 16 minutes
This film shows how science makes it possible for those who lose their limbs by amputation or accident to adjust themselves to old or new occupations
Artificial limbs and special training centers are the means to this goal
Prepared by British Information Services 30 Rockefeller Plaza, New York 20

Blood Transfusion

Silent 16 mm 1 large reel 1,200 feet
Running time about 45 minutes
Three methods of blood transfusion illustrated in detail
Sponsored by the Blood Transfusion Betterment Association 39 East 78th Street, New York
Produced by Mr Joseph P Hackel, New York

Eyes for Tomorrow (1944)

Sound 16 mm 1 reel
Running time about 15 minutes
This stresses good general health as a prerequisite for good eyesight
It also deals with the importance of antepartum care as a means of reducing the amount of blindness caused by syphilis and gonorrhea, the conservation of vision among school children, the use of sight saving glasses for children with seriously defective vision, the necessity for regular eye examinations, methods of treating glaucoma and trachoma, and the eye hazards of industry
Produced by National Society for the Prevention of Blindness, Inc, 1790 Broadway, New York 19

Keep 'Em Out (1942)

Sound 16 mm, 1 reel, 325 feet
Running time about 15 minutes
The film describes the economic damage and health hazards caused by rats
Produced by Stark Films, 537 North Howard Street, Baltimore 1, in cooperation with U S Public Health Service

Medical History in Clinical Teaching (1940)

Silent 16 mm 2 reels, about 300 feet each
Running time about 25 minutes
History of physical diagnosis with scenes from the lives of Hippocrates, William Harvey, Rev Stephen Hales, Leopold Auenbrugger von Auenbrug, Rene Theophile, Hyacinthe Laennec and Wilhelm Konrad Roentgen
Prepared by Department of Cardiology, Woman's Medical College of Pennsylvania, Philadelphia

Physical Diagnosis (a presentation of advanced and unusual cases with physical signs demonstrable by inspection) (1942, revised 1945)

Silent Color 16 mm, 17 reels, 400 feet each
Following are the subjects and the approximate running time of the various reels
Abnormalities in Gait Reel 1 15 minutes
Other Types of Involuntary Movement Reel 2 15 minutes
Endocrine Diseases with Characteristic Physiognomy Reels 3 and 4 30 minutes
Abnormalities in Color Reel 5 15 minutes
Head and Face Reels 6, 7 and 8 45 minutes
Neck Reel 9 15 minutes
Chest Reels 10 and 11 25 minutes
Displacement of the Apical Impulse Reel 12 10 minutes
Abdomen Back and Perineum Reels 13 and 14 25 minutes
Extremities Reels 15, 16 and 17 40 minutes
Produced by Dr Gordon B Myers, Dr Fred J Margolis and Dr Muir Clapper, Wayne University College of Medicine, Detroit

Syphilis—A Teaching Film (1942)

Sound 16 mm, 3 reels
Part A Diagnosis of Early Syphilis, 18 minutes
Part B Diagnosis of Latent Syphilis, 14 minutes
Part C Management of Syphilis, 29 minutes
Prepared by United States Public Health Service

The Hygiene of Swimming

Silent 16 mm 1 reel 400 feet
Running time 15 minutes
This picture shows that man is not adapted to aquatic life and illustrates the danger of infection to the ear, nose and throat, the danger of diving in shallow water and the danger of chilling from cold water
Prepared by Dr H Marshall Taylor, Jacksonville, Fla, for the Section on Laryngology, Otology and Rhinology of the American Medical Association

The Life History of the Rocky Mountain Wood Tick (1939)

Silent Color 16 mm 2 reels 400 feet each
Running time about 25 minutes
The tick is listed as the vector of (1) Rocky Mountain Spotted Fever, (2) tularemia, (3) Colorado tick fever, (4) American Q fever and (5) tick paralysis
There are many views of landscapes showing the type of foliage wherein the ticks are commonly found, as well as of the various wild and domesticated mammals which serve as hosts for the blood meals necessary for the development of the ticks
Produced by The Rocky Mountain Laboratory of the U S Public Health Service, Hamilton, Mont

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Thomas Addis, professor of medicine, Stanford University School of Medicine, San Francisco, was on July 17 chosen a fellow of the Royal College of Physicians of Edinburgh.

Fund Named for Ruby Cunningham.—Almost \$7,000 has been donated to establish a memorial in honor of Dr. Ruby L. Cunningham, late senior physician at the Ernest V. Cowell Memorial Hospital, Berkeley. The fund will be known as the Ruby L. Cunningham Fund and will be used in connection with the student health service for "extraordinary demands" which could not be met through ordinary channels.

Robert Millikan Retires.—Robert A. Millikan, Sc.D., has retired as administrative head of the California Institute of Technology, Pasadena. He will continue as vice president of the board of trustees and assist the president of the board in public relations work and institutional development as well as devote much time to his own research and writing. Max Mason, Sc.D., Pasadena, has also retired as a member of the executive council.

Regulation Concerning Hycodan.—Hycodan will be treated under the state narcotic act as codeine, with the exception of exemption, according to recent regulations of the state division of narcotic enforcement. Prescriptions calling for hycodan in combination with other nonnarcotic medicinal ingredients may be written on the ordinary single prescription blanks of physicians but may not be refilled. Hycodan is not exempt in any amount from the writing of a prescription by the physician prescribing it.

DISTRICT OF COLUMBIA

Clinic for Alcoholics.—As a step toward the formation of a mental hygiene clinic service the District of Columbia Health Department has organized a clinic for alcoholic addicts. Dr. Michael M. Miller, a member of the staff of St. Elizabeths Hospital, who formerly developed a clinic for alcoholic addicts in Cleveland, has been secured on a volunteer basis for two clinic sessions weekly. Other personnel are on a volunteer basis and have been recruited from Alcoholics Anonymous. Service in the local health department must meet Civil Service requirements and the arrangement, therefore, in regard to the staffing of the clinic has been adopted as a temporary measure. Patterned in a general way after the Yale University Clinic for Alcoholics, the clinic saw 275 patients between August 6, the day of its opening, and August 20. Acute alcoholic addicts are referred to the Gallinger Municipal Hospital for detoxication purposes, following which the psychiatric clinic service takes over and uses members of Alcoholics Anonymous for whatever moral support the group can give to the patient. Nonacute cases, however, not requiring institutionalization are carried by the use of sedation and stimulants as required.

ILLINOIS

Personal.—Dr. Robert K. Campbell, Springfield, medical director of St. John's Sanatorium, crippled children's school and hospital, on August 7 observed his twenty-fifth anniversary as a member of the staff.

Chicago

Talk on Cancer.—A series of popular medical lectures at the Museum of Science and Industry (THE JOURNAL, July 28, p. 962) has been so acceptable that, by request of the audience, one on cancer was added August 29 with Dr. Herbert E. Schmitz, professor and head of the department of obstetrics and gynecology at Loyola University School of Medicine, as the speaker. Dr. H. William Elghammer, professor of pediatrics at Loyola, gave a talk August 22 on "Rheumatic Fever in Childhood."

Herbert Kobes Named Director of Crippled Children's Services.—Dr. Herbert R. Kobes, director of medical services, Maine Department of Health and Welfare, Augusta, Maine, has been appointed director of the division of services for crippled children of the University of Illinois, with central offices in Springfield at 1105 South Sixth Street. He succeeds

Lawrence J. Linck, who recently resigned to become executive director of the National Society for Crippled Children (THE JOURNAL, August 11, p. 1117).

A New Residency in Anesthesiology.—The surgery department of the University of Chicago School of Medicine is establishing a new three year residency in anesthesiology. A part of the time will be devoted to research and the remainder to clinical work. This residency will be under the supervision of both Dr. Huberta M. Livingstone, associate professor of surgery and director of anesthesiology, and Dr. Eugene M. K. Geiling, professor and chairman of the department of pharmacology. Requests for information regarding this residency should be sent to Dr. Livingstone.

INDIANA

One Hundred and One Years of Age.—Dr. Henry C. Rogers, Rockville, observed his one hundred and first birthday, August 16. Dr. Rogers graduated at the Indiana Medical College, Indianapolis, in 1876.

New Board of Health and Hospitals.—Dr. Herman G. Morgan was recently appointed secretary of the newly created Indianapolis Board of Health and Hospitals and director of public health. The board was established by the last legislature and supplants two separate boards. Other appointees include Drs. Charles W. Myers, director of hospitals; Kenneth G. Kohlstaedt, medical director of the Indianapolis City Hospital; James D. Peirce Jr., assistant director of the hospital, and Gerald F. Kempf, superintendent of preventive medicine.

Health Center Under Construction.—Under the direction of the Indianapolis board of health, the construction of a health center building as an adjunct to Flanner House was begun on June 13. The building will cost approximately \$105,000, with an additional \$20,000 to be spent for equipment, and will contain clinic, examination and x-ray rooms and offices for staff members. The work will be tied up with the city's slum clearance project, and, in addition to diagnosis of the causes, particularly from the standpoint of housing and environment, a case-finding program of tuberculosis, venereal diseases, antepartum medicine, infant and child health, dental and general medicine will be conducted.

MINNESOTA

Personal.—Dr. Ruth Evelyn Boynton, Minneapolis, was recently elected president of the Minnesota Department of Health.—Dr. Elmer Mendelsohn Jones, St. Paul, has been appointed a member of the state board of medical examiners to succeed the late Dr. Max W. Alberts, St. Paul.—Dr. David E. Ellison has resigned as venereal disease control officer of the Minneapolis Department of Health, effective September 1.

Sentenced for Operating Clinic in "Bloodless Surgery."—On July 17 "Dr." Albert Henry Broden, "naturopathic physician," Milwaukee, pleaded guilty to an information charging him with practicing healing without a basic science certificate in the district court of Hennepin County, Minn. Broden was sentenced to a term of one year in a Minneapolis workhouse, the sentence being stayed on condition that Broden "immediately leave the state and stay out." Broden was arrested by Inspector Bernath of the Minneapolis police department after a joint investigation by the Minnesota State Board of Medical Examiners and the Minneapolis police department on July 14 at the Hotel Andrews, where he was conducting a so-called "clinic" in "bloodless surgery." Broden admitted to the court that he charged \$150 for each person who attended his clinic. His records show that he obtained \$600 from three chiropractors and one masseur. Broden, who represented himself as a "naturopathic physician," was arrested in Duluth in 1929 and convicted even though he took his case to the supreme court of Minnesota. He is said to have three convictions in Texas for violating the medical laws.

MISSOURI

William Cramer Dies.—William Cramer, Ph.D., research associate, Barnard Free Skin and Cancer Hospital, St. Louis, died in Denver August 10, aged 67. Dr. Cramer, research associate in cytology, Washington University School of Medicine, St. Louis, had been senior member of the scientific staff for the Imperial Cancer Research Fund in London from 1915 to 1939, when he came to the United States.

Medical Curriculum Revised.—All didactic work of the third year at Washington University School of Medicine, St. Louis, will be consolidated into a single conjoint course in medicine. This means that a disease will be discussed simul-

taneously by all of the departments concerned and the student will be given a complete picture of the disease. Another innovation is the rearrangement of the clerkships of the third and fourth years so as to make possible a clinical clerkship in preventive medicine. To do this the third year has been divided into quarters instead of trimesters as in the past. The elective quarter in the senior year remains. These departures are the result of a survey made by a subcommittee of the committee on medical education at the medical school.

MONTANA

State Medical Election.—Dr. Maurice A. Shillington, Glendive, was named president-elect of the Montana State Medical Association at its annual meeting July 15, and Dr. Sidney A. Cooney, Helena, was inducted into the presidency. Dr. Walter H. Stephan, Dillon, is vice president, and Dr. Raymond F. Peterson, Butte, was reelected secretary-treasurer.

Honorary Membership Awarded for Cancer Work.—The Montana State Medical Association has awarded honorary membership to Mrs. H. W. Peterson, Billings, field commander, northwest region, Field Army, American Cancer Society, and president of the Public Health League of Montana, for "unselfish devotion and outstanding accomplishments of the officers and members of the Montana division, American Cancer Society, in the field of cancer prevention and public health." The presentation was made to Mrs. Peterson by Dr. James C. Shields, Butte, president of the state medical association, at a banquet of its house of delegates.

NEBRASKA

Neuropsychiatry Foundation Organized.—The A. E. Bennett Neuro-Psychiatry Foundation, a nonprofit organization to conduct research into the cause, prevention and treatment of neurologic and psychiatric diseases, has been chartered in Nebraska and is functioning at the Bishop Clarkson Memorial Hospital, Omaha. Charter members include Dr. Abram E. Bennett, associate professor of neuropsychiatry, University of Nebraska College of Medicine; Dr. Paul T. Cash, now a major in the Army on duty in the neuropsychiatric service at Camp Carson, Colorado; Foster E. Bennett, Dr. Bennett's son, a student at Dartmouth Medical School, Hanover, N. H.; Fred W. Thomas, Omaha, a vice president of the First National Bank; Carl Falk, Omaha, president of Buffet & Co., and Fred N. Hellner, Omaha, attorney. The organization is the outgrowth of activities of the Fevcr Therapy Research Department of the University of Nebraska College of Medicine, conducted the past ten years at the hospital under the direction of Dr. Bennett. Besides research, the foundation will train residents or fellows selected by its trustees and finance specified students in graduate work in neuropsychiatry. The facilities at Clarkson, where a whole floor is given over to the neuropsychiatric division, will be used. A private fund of \$25,000 will be taken over by the foundation. Members of the advisory board will be Charles F. Kettering, D.Sc., director of research for General Motors Corporation; Dr. Ladislav J. Meduna, associate professor of psychiatry, University of Illinois College of Medicine, and Dr. Hans H. Reese, professor of neuropsychiatry, University of Wisconsin Medical School, Madison. Besides Dr. Bennett, director, the staff now includes Dr. Cornelia B. Wilbur, woman associate, and Dr. R. de la Fuente, graduate of the University of Mexico, and nurses.

NEW YORK

Charles Carpenter Goes to Philippines.—Dr. Charles M. Carpenter, associate professor of bacteriology and public health, University of Rochester School of Medicine and Dentistry, Rochester, has been sent to the Philippine Islands on a special medical mission by the Office of Scientific Research and Development. In cooperation with the medical corps of the Army, Dr. Carpenter will make an investigation of venereal diseases, on which he is a special consultant for the U. S. Public Health Service.

Cancer Teaching Evening.—On October 9 a "cancer teaching evening" will be held at the Rochester Academy of Medicine under the auspices of the Medical Society of the County of Monroe, the academy of medicine, the Seventh District Branch of the state medical society, the University of Rochester School of Medicine and Dentistry, the Tumor Clinic Association of the State of New York, the state medical society and the division of cancer control of the state department of health. The speakers will be Drs. John H. Garlock, New York, on "Carcinoma of the Colon" and John J. Morton Jr., Rochester, "Progress in Cancer Research."

Personal.—Dr. Nelson G. Russell, Buffalo, was honored with a specially called meeting of the city's advisory health board in recognition of his fiftieth anniversary of graduation from medical school. Dr. Russell is chairman of the advisory health board (*THE JOURNAL*, April 7, p. 934).—Homer L. Sampson, D.Sc., director of the x-ray laboratory at Trudeau Sanatorium, Trudeau, died in the Physicians Hospital, Plattsburg, May 16.—John M. McKibbin, Ph.D., instructor in nutrition, department of biochemistry, Harvard Medical School, Boston, and the School of Public Health, has been appointed assistant professor of physiologic chemistry at Syracuse University College of Medicine, Syracuse.

State Buys Sanatorium for Veterans.—New York State has agreed to purchase the \$3,600,000 Metropolitan Life Insurance Sanatorium at Mount McGregor for \$350,000 for use as a rest camp for returning New York veterans. At least 500 veterans can be accommodated on the property at one time. The sanatorium consists of seventy-five buildings and 1,500 acres, including a modern 421 acre dairy and poultry farm, and has been maintained since 1913 for Metropolitan employees, especially those with tuberculosis (*THE JOURNAL*, June 30, p. 679). Under a recently enacted law appropriating \$2,825,000 for veterans' assistance (*THE JOURNAL*, May 12, p. 144) the state was authorized to provide rest camps for returning veterans. It had been planned to have more than one camp, but Governor Dewey, in a statement to the press, said that the Mount McGregor camp is so large and so well equipped that it would obviate the need for additional camps.

New York City

Goldwater Fellows Named.—Dr. I. Norwich, assistant superintendent, Johannesburg Hospital, Johannesburg, South Africa, will fill one of the first S. S. Goldwater fellowships in hospital administration at Mount Sinai Hospital, according to the *Modern Hospital*. The fellowship permits one year of study and observation at Mount Sinai (*THE JOURNAL*, March 20, 1943, p. 960). Dr. Norwich, who is to arrive in the fall, is a native of Johannesburg and has done graduate medical study in England. Another fellowship has been granted to Marguerite M. Ducker, research assistant in the program in hospital administration at Northwestern University, Chicago. On completion of the fellowship, Miss Ducker is expected to return to the teaching staff in hospital administration at Northwestern.

Study of Alcoholic Addicts.—The New York Academy of Medicine, through one of its subcommittees, is carrying on a survey on the care and treatment of alcoholic addicts. Questionnaires have been sent to physicians in the city and to every hospital, sanatorium and other type of health facility treating inpatients. The physicians were asked whether they treat alcoholic addicts, whether they do so at special hours, what institutional facilities and treatment they use, what auxiliary organizations they use and what in their judgment is the best way to deal with the problem of the alcoholic addict. The hospitals were asked whether they treat alcoholic addicts for complications of diseases, sobering up or for the addiction, how many patients are treated, in what proportion in the acute cases are requests made for treatment for addiction, what treatment is used and whether follow-up services are provided. Results of the questionnaires will be compiled in a report which is expected to be available late in the fall.

OHIO

The Stone Memorials.—According to the *Ohio State Medical Journal* \$25,000 has been presented to the Ohio State University College of Medicine by Franz T. Stone, Columbus, in honor of the ninetieth birthday of his father, Julius T. Stone, former member and chairman emeritus of the university's board of trustees. One gift of \$20,000 will create the Julius F. Stone Fund for Medical Research, the income to be used particularly for research in the field of physical medicine. The second gift, \$5,000, creates the Julius F. Stone Medical Fellowship for research in the division of physical medicine. The first recipient of the fellowship is Dr. William G. Myers, a research associate in the department of bacteriology.

Health Legislation.—A bill has been enacted, effective October 12, authorizing the Ohio Department of Health to devise a suitable program for establishing a blood bank for civilian use. Another bill, effective September 10, provides for about \$1,000,000 to improve the state program for control and elimination of Bang's disease in cattle. Newly enacted legislation, effective October 11, changes the name of the division of mental diseases to the division of mental hygiene. An appropriation of \$5,000,000 is allotted under House Bill 477 for

improvements in and expansion of the facilities of the colleges of medicine and dentistry at Ohio State University, Columbus, and for the construction of a new hospital for clinic teaching and research.

Gifts to Western Reserve.—The Beaumont Foundation has given \$220,000 to Western Reserve University. One hundred thousand has been designated for application toward the cost of a new building to be constructed by the School of Applied Social Sciences, which will ultimately cost about \$500,000. One hundred thousand will be devoted toward research in the department of pathology in the medical school and \$20,000 will be applied to help finance a project to be undertaken jointly by Western Reserve University and the Cleveland Hearing and Speech Center. A portion will be used for completing and remodeling the new headquarters of the center (*THE JOURNAL*, June 9, p. 453) and the remainder for research and training of teachers in speech and hearing work. Both gifts were made in memory of Dudley, deceased son of the late Commodore Louis D. Beaumont, the latter having been in earlier years a resident of Cleveland and one of the founders of the May Company. The gift to the university was made through Nathan L. Dauby, Morton J. May and Nathan Loeser, trustees of the Beaumont Foundation.

OKLAHOMA

Progress of Public Relations Program.—The Oklahoma State Medical Association has organized a speaker's bureau consisting of more than 200 members of the medical profession as a part of its recently developed public relations program (*THE JOURNAL*, July 14, p. 819). Sixty-two laymen, including the governor, the president of the state university and the president of the Oklahoma Agricultural & Mechanical College, have agreed to participate. The general educational program includes:

Public education through the press, radio, motion pictures, and a speaker's bureau.

Postgraduate program to the doctors of the state, refresher courses from the state medical school, residencies and cooperation with the state medical school in added facilities, including research facilities, for returning service men and civilian doctors.

Postwar planning for the placement of doctors now in the armed services.

Intimate contact between the state association and county medical societies.

The program was initiated by a series of meetings in eight councilor districts, the remaining two districts to hold meetings in September.

PENNSYLVANIA

Ninety-Nine Years of Age.—Dr. Frank F. Frantz, Lancaster, observed his ninety-ninth birthday July 19. He is said to be the oldest living graduate of Jefferson Medical College of Philadelphia, receiving his degree in 1869.

Philadelphia

University News.—Under the will of the late Dr. Julius D. Love, Temple University School of Medicine, ultimately will receive one half of his \$70,000 estate. Until his death, July 4, Dr. Love had been practicing in Philadelphia for more than fifty-two years.

Personal.—Sir Alexander Fleming has been granted honorary membership in the Philadelphia College of Pharmacy and Science.—Dr. John Hart Toland has been appointed special assistant in the division of medical services of the board of education.—Dr. and Mrs. Charles Price Mercer recently celebrated their fiftieth wedding anniversary.

Memorial to Physician.—A gift of \$500 was recently presented as a memorial by the faculty and friends of Dr. Eleanor H. Balph to the Woman's Medical College of Pennsylvania. Dr. Balph was assistant professor of gynecology at the college at the time of her death in May. Dr. Mary M. Spears gave a similar gift in memory of Lieut. William McIndoe Spears Jr., Inf., Army of the United States.

RHODE ISLAND

Society Observes Fiftieth Anniversary.—The Pawtucket Medical Association stemmed from a Medical Science Club organized in Pawtucket in 1894, according to a review of the society's development presented by Dr. William N. Kalcounos, president of the society, as a feature of the society's fiftieth anniversary celebration on June 6. Dr. Charles F. Sweet is the only surviving member of the association, which held its first meeting and election of officers in March 1895. Dr. James L. Wheaton, who joined the association in 1895, was presented with a scroll at the celebration. A similar honor was to be made to Dr. Sweet, who was unable to attend.

TEXAS

Crippled Children Services Transferred to Health Department.—The transfer of the responsibility for administration of the Texas program of services to crippled children from the state department of education to the state department of health was recently authorized.

Changes at Southwestern Medical College.—Dr. Art Grollman, professor of experimental medicine, Southwest Medical College, Dallas, has been named professor of medicine and chairman of the department of experimental medicine. Simon Edward Sulkin, Ph.D., associate professor of bacteriology and immunology, has been named professor and acting chairman of the department. Dr. George T. Caldwell, professor of pathology, has been granted a year's leave of absence.

Hermann Professional Building.—A fourteen story building for offices of doctors and dentists to cost \$1,500,000 is being planned for a site adjacent to Hermann Hospital, Houston, newspapers report. The structure will be connected with Hermann Hospital by a tunnel and will be known as the Hermann Professional Building. Present plans call for a penthouse on the fourteenth floor, which will be available for a doctors' club. Tentative reservations for more than 70 per cent of the building space have already been made, it was stated. Another unit of Hermann Hospital is also planned. It will be located on a site between the proposed professional building and the present Hermann Hospital.

Judson L. Taylor Foundation.—The incorporation of the Judson L. Taylor Foundation has been announced. The group which will assist young surgeons to obtain advanced training and provide lectures by eminent surgeons, honors Dr. Taylor who died Nov. 28, 1944 of coronary occlusion while serving as a commander in the medical corps of the U. S. Navy. Dr. Taylor had served as president of the Harris County Medical Society and of the State Medical Association of Texas. He had also been a founder member of the American Board of Surgery. Friends who wish to contribute to the memorial to Dr. Taylor may address the Judson L. Taylor Foundation, 229 Medical Arts Building, Houston 2.

WISCONSIN

Cancer Detection Center.—The Medical Society of Milwaukee County some four months ago opened a cancer Detection Center. Space was provided in the student health center annex to the Marquette University School of Medicine, but the project has met with such good response that permanent offices are now being considered in connection with the executive headquarters of the medical society, with a full time medical secretary to answer inquiries and handle case records and follow-ups. Of the 798 persons seen during the first three months of operation, 41 received definite diagnosis of cancer. 18 of these had not been diagnosed previously. In addition to the 41, 74 persons with suspected cancer were seen and 86 gastrointestinal x-rays were recommended.

License Law Now Includes Suspension Clause.—The governor recently signed a law providing that the authority having the power to revoke a physician's license shall also have the power to order its suspension for a period not to exceed two years. The measure was suggested by the state board of medical examiners, and its introduction was authorized by the committee on public policy of the Wisconsin State Medical Society. The old law stipulated that the state board of medical examiners shall revoke the license of a physician convicted of a crime in the course of his professional conduct, and, by action brought for the purpose, a license may be revoked by a circuit court. Under the law many actions were deferred or delayed because law enforcement agencies felt the penalty of revocation was too severe although, in most cases, it was believed that some penalty should be provided.

Faculty Changes at Marquette.—Dr. William A. Douglas Anderson, associate professor of pathology, St. Louis University School of Medicine, St. Louis, since 1940, has been appointed professor of pathology and bacteriology and director of the department at Marquette University School of Medicine, Milwaukee, effective about October 1. Dr. Anderson, who graduated at the University of Toronto Faculty of Medicine in 1934, will also be pathologist at St. Mary's Hospital, Milwaukee. Dr. Samuel B. Pessin, Madison, who graduated at Marquette in 1929, has been appointed associate professor of pathology and bacteriology, also effective about October 1. Michael Laskowski, Ph.D., associate professor of physiologic chemistry at the University of Arkansas School of Medicine, Little Rock, has been appointed associate professor of biochemistry at Marquette University. He succeeds Thomas W. Ray, Ph.D., who retired because of ill health.

GENERAL

Student Health Activities.—New student health service buildings are being planned for the University of Alabama, University; University of Colorado, Boulder; Connecticut College, New London; University of Delaware, Newark, and the University of British Columbia.

Directory of Medical Women.—The first directory of medical women of the United States and its possessions is announced by the *Medical Woman's Journal*. The directory carries about 7,000 names of women physicians listed in alphabetical and geographic divisions.

Porter Fellowship Stipend Increased.—The Porter Fellowship, awarded by the American Physiological Society, which has been carrying an annual stipend of \$1,200 given by Dr. William T. Porter of the Harvard Apparatus Company, Boston, has been increased by Dr. Porter to \$2,400 annually. The fellowship, which has not been given since 1941, will be resumed in 1946.

Committee to Survey Health Problems in France.—A three member American Red Cross delegation has been named to survey child health problems in France at the invitation of the French government. Members of the committee include Louis I. Dublin, Ph.D., vice president, Metropolitan Life Insurance Company, New York; Dr. Leona V. Baumgartner, pediatrician on leave from the New York City Department of Health, and Mrs. Ida K. Fivian, instructor in foreign languages at the Bradford Junior College, Bradford, Mass.

Theobald Smith Gold Medal Awarded.—The American Academy of Tropical Medicine has announced that the Theobald Smith Gold Medal will be awarded to Dr. Charles M. Wenyon, protozoologist and retired director of the Wellcome Foundation Research Laboratories of London. *Tropical Medicine News* reports that because Dr. Wenyon's health is not in sufficiently good condition for him to make a journey to the United States to receive the award, arrangements will be effected for a presentation in London through the U. S. Embassy.

Journal of Gerontology.—The Gerontological Society, an outgrowth of the American Division of the Club for Research on Ageing, founded in 1939, plans to establish the *Journal of Gerontology*, to be issued quarterly beginning during the first quarter of 1946. According to *Science*, the committee on publications consists of Dr. Roy G. Hoskins, Harvard Medical School, Boston, chairman; Lawrence K. Frank, New York; Dr. William de B. MacNider, University of North Carolina School of Medicine, Chapel Hill, and Dr. Edward J. Stieglitz, Washington, D. C. The editor-in-chief is Dr. Robert A. Moore, Washington University School of Medicine, St. Louis.

Narcotic Violations.—The U. S. Bureau of Narcotics announces the following actions:

Dr. Addison G. Moore, Indianapolis, was convicted in the U. S. District Court at Indianapolis for violation of the federal narcotic law and on July 21 was sentenced to a prison term of one year and one day.

Dr. John C. Bigham, Batesville, Ind., pleaded guilty in the U. S. District Court at Indianapolis to violation of the federal narcotic law and on June 30 was sentenced to pay a fine of \$250.

Dr. James W. Benham, Columbus, Ind., pleaded guilty in the U. S. District Court at Indianapolis to violation of the federal narcotic law and on June 30 was sentenced to pay a fine of \$300.

Dr. Alma Alphonso Thorum, Spring City, Pa., was convicted in the U. S. District Court at Philadelphia on July 16 of a narcotic violation and was sentenced to serve a prison term of one year and one day.

Dr. Henry M. Bankhead, Fulton, Mo., pleaded guilty in the U. S. District Court at St. Louis to a violation of the federal narcotic law; sentence was suspended and he was placed on probation for five years, one of the provisions of which was that he enter the U. S. Public Health Service Hospital, Lexington, Ky., and remain there until discharged.

Dr. Raymond O. Cheney, Live Oak, Fla., was convicted in the Dade County, Fla., Court of Criminal Record for violation of the Florida Uniform Narcotic Drug Act; on June 26 imposition of sentence was deferred from day to day and term to term until the further order of the court.

March of Dimes Totals Almost Seventeen Million.—A total of \$16,589,874 was contributed to the 1945 March of Dimes for the National Foundation for Infantile Paralysis, as against \$10,973,491 for 1944. Of the total amount of funds raised, 50 per cent is allotted to national headquarters of the foundation to finance research into the cure and prevention of infantile paralysis and a broad educational program which includes scholarships and fellowships in orthopedic nursing, physical therapy, orthopedic surgery, virology and health education, as well as to maintain an emergency epidemic fund to aid county chapters in areas hard hit by outbreaks of the disease. The other half of the March of Dimes funds is retained by county chapters of the National Foundation to carry on year round services to infantile paralysis victims in the 3,070 counties of the United States. George H. La Porte, who joined the foundation in 1941 as director of fund raising publications and public displays and who in 1943 was named

director of the Greater New York fund raising division, has been named director of public relations for the foundation. The first Roosevelt memorial two cent stamp was sold August 24 to Basil O'Connor, president of the foundation, at a special ceremony at Warm Springs, Ga. During the ceremony copies of the stamp were presented to each of the patients at the foundation. The stamp is rectangular, bearing a picture of the "Little White House" on the right and an oval of President Roosevelt on the left.

CANADA

Minister of Health Named Professor.—Dr. Reginald P. Vivian, Port Hope, Ont., minister of health of Ontario, has been appointed to the chair of hygiene and social medicine of McGill University Faculty of Medicine, Montreal, Que., and will take over his activities in September.

The Louis Gross Memorial Lecture.—The eighth annual Louis Gross Memorial Lecture will be delivered at the Jewish General Hospital, Montreal, October 17, by Dr. Paul Dudley White, Boston. His subject will be "The Heart in Hypertension Since the Days of Richard Bright."

The Lamont Memorial Prize.—In memory of his father Dr. Joseph Laurie Lamont, assistant chief medical officer, department of veterans' affairs, Winnipeg, has given \$3,000 to the University of Manitoba, the proceeds of which are to be used to provide the Dr. T. J. Lamont Memorial Prize. The new award will be offered every alternate year for an essay or report on original work or investigation on maternal and neonatal welfare. Competition will be open to graduates in medicine of the University of Manitoba up to the fifth medical year, according to the *Canadian Medical Association Journal*.

CORRECTION

Eradication of Yellow Fever.—The Washington Letter in THE JOURNAL, August 18, contained a statement attributed to Dr. Fabio Carneiro de Mendonca which indicated that UNRRA will shortly inaugurate a world campaign for the eradication of yellow fever and that the disease is quite prevalent in the islands of the Pacific. Yellow fever is not and has not been prevalent in the islands of the Pacific. It is understood that Dr. Mendonca came to this country as a quarantine expert to discuss the extent of the endemic yellow fever area in Brazil. So far as is known, UNRRA does not intend to inaugurate a worldwide campaign to eradicate yellow fever.

Government Services

Two Man Committee to Survey Navy Hospitals

Dr. Basil C. MacLean, professor of hospital administration, University of Rochester School of Medicine and Dentistry, and director of Strong Memorial Hospital, Rochester, N. Y., and William M. Stevenson, New York, who for two years has been director of Red Cross activities in England, Africa and Italy, have been named to a two man committee to survey navy hospital facilities in the country.

Class for Laboratory Technicians

On October 1 the first class for state laboratory technicians on tropical diseases will be opened as part of a program recommended during the November 1944 meeting of the American Society of Tropical Medicine. When petitioned, Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, agreed to sponsor the program of organizing teaching teams, to disseminate material on tropical diseases and, in addition, to form a library of teaching films to be lent to medical societies and other appropriate organizations. Dr. Louis L. Williams Jr., medical director, U. S. Public Health Service, was assigned to formulate plans. The program has recently been transferred to the Office of Malaria Control in War Areas (of the States Relations Division) in Atlanta with Surgeon William S. Boyd, U. S. Public Health Service Reserve, in charge. The Atlanta unit will set up expanded laboratory facilities to offer intensive training in the laboratory diagnosis of tropical diseases, to serve as a diagnostic center for examination of specimens referred by state departments of health and for examinations of diagnostic materials obtained for survey purposes and to make available to technicians in state and local health department laboratories diagnostic and reference materials.

The Shortage of Doctors and the Coming Winter

Considerable concern is felt in the medical profession about doctors' work in the coming winter, which will have to be performed by a profession depleted by the call of the fighting services. The government has refused to make any promises as to demobilization until the war in the Far East is definitely over. Also the occupation of Germany will require the maintenance of a large army. We have been warned to expect a hard winter with a shortage of coal. People are coming back to their old homes no matter in what condition they have been left by German bombing. Overcrowding is inevitable, for many houses have been completely destroyed and there is great shortage of labor in the building trade. Young married people just starting are unable to obtain homes and have to crowd into the homes of relatives. Psychologic upsets and troubles are bound to arise when some men return to their wives and families after years of absence in the forces. The civilian doctor has had a hard time during the war, but it is felt that his hardest time may be in front of him. Before the war the average number of patients per doctor was 1,800; now it is something like 3,500. The British Medical Association has asked for the release from the forces of at least 5,000 doctors before the winter sets in. One London doctor has said "Last week I was the only doctor in my district for well over 10,000 patients, owing to one of my colleagues being ill and another away on holiday."

Full Time Thoracic Surgeons to Be Appointed by the London County Council

The London County Council proposes to appoint for its hospitals two full time thoracic surgeons, of whom the senior will be known as the chief thoracic surgeon. This position has arisen because the comparatively few surgeons available who are competent to undertake this branch of surgery look with disfavor on the sessional rates of remuneration offered by the council: \$15 a session in hospitals within the London area and \$30 in hospitals and sanatoriums in outer London. During a recent year the total expenditure on fees to five part time thoracic surgeons was \$2,900 for 532 sessions. A salary scale substantially higher than that paid by the council to full time surgeon specialists, \$6,250 rising by increments of \$250 to \$7,500 a year, is considered necessary to attract a thoracic surgeon of adequate experience to the post of chief thoracic surgeon. For him, therefore, a salary of \$10,000 rising by annual increments of \$500 to \$12,500 is proposed. The scale for the other thoracic surgeon will be the same as for the surgeon specialists.

International Congress of Obstetrics and Gynecology to Mark the Bicentenary of the Rotunda Hospital

The Rotunda Hospital, Dublin, was founded in 1745 by a physician, Bartholomew Mosse, and is the oldest maternity hospital in the British Isles. Its fame as a teaching center is widespread, and students come to it from all over the world. Its bicentenary falls this year, but, in consequence of the disturbance produced by the war, celebration is deferred until the second week of July 1947, when an International Congress of Obstetrics and Gynecology will be held in Dublin, primarily under the auspices of the Rotunda Hospital, but with the cooperation of the other two Dublin maternity hospitals. The principal subjects contemplated for discussion are eclampsia, sepsis, obstetric shock, fetal mortality and the modern approach to the problem of sterility.

PALESTINE*(From Our Regular Correspondent)*

JERUSALEM, June 1, 1945.

An Epidemic of Eosinophilic Erythredema, Possibly Early Filariasis

In a lecture held at the Jewish Medical Association in Tel-Aviv on February 21 A. Klopstock and H. Steinitz reported their observations and studies on a syndrome previously unknown in Palestine. Steinitz reported as the clinical features cutaneous manifestations in the form of swellings and blood changes consisting of leukocytosis with eosinophilia.

The cutaneous swellings are red and hot, similar to erysipelas, occasionally also to urticaria or erythema nodosum. They are of a transient nature persisting, however, three to five days and more and migrating over wide areas of the body. The swelling may be small but may also spread over an entire extremity. Localization on the mucous membranes, lymphangitis or enlargement of nodes is rare. The characteristic migration of the swellings may continue over weeks and months, with normal intervals of a few weeks, followed by a recurrence. In some instances the same region was several times attacked.

The swelling is accompanied by severe itching and occasionally pain.

As regards blood changes, there is frequently leukocytosis, as a rule between 12,000 and 15,000, but counts up to 30,000 have been recorded. The number of eosinophils is almost invariably increased, ranging between 15 and 35 per cent but reaching values of over 50 per cent with considerable variations in one and the same case. Numerous eosinophils have also been found in sternal and tissue puncture. The red blood cell count is normal, the blood sedimentation rate normal or slightly accelerated. Examinations of the urine and the feces are normal. Other findings, including x-ray examinations of the chest, reveal nothing out of the ordinary. The temperature is normal or slightly increased (seldom short attacks of fever when swelling starts); nevertheless the majority of patients complain of general discomfort and of inability to attend to their work.

There may be prodromes, as "rheumatic pains" or general malaise. Although the disease is not apparently of a serious nature, general discomfort as well as long standing and special localization of the swellings may have a bad influence on the general condition.

In the discussion a number of physicians were able to confirm these observations, especially Leffkowitz and Sukiennik, whose papers, as well as those of Klopstock and Steinitz, were published in *Harefuah*, March 15. Larger numbers of cases have been noted since November 1944, but sporadic cases certainly have occurred in the past few years. After the first cases had made their appearance in Tel-Aviv and its neighborhood others were reported from Jerusalem and a few from rural settlements. Recently Lyon and Kleinhaus (*Acta med. orient.*, May) gave an account of their observations in Jerusalem, among them 2 cases with transitory pulmonary infiltrations (Loeffler's syndrome). The total number of cases in Palestine may amount to about 200. Children are only exceptionally attacked.

According to Klopstock, who studied the epidemiologic aspects, it is certain that we are dealing with an allergic phenomenon and that the clinical picture is strikingly similar to "Calabar swelling," the allergic phase of filariasis. It should be borne in mind that war conditions have increased the possibilities of infection with filariae in this country, which until now had been free from this disease. But so far no microfilariae could be found in spite of repeated examinations of the blood and of tissue puncture; biopsies did not reveal parasites either. Skin tests could not so far be carried out, but it is to be hoped that filaria antigen will be available in this country in the near future; only then will it be possible to decide whether or not

this disease constitutes an early stage of a filaria infection. At present the etiology remains obscure. For practical purposes Klopstock and Steinitz suggest the name of eosinophilic erythredema for this disease.

BUENOS AIRES

(From Our Regular Correspondent)

July 16, 1945.

Effect of Alloxan on Glycemia in Dogs

Dr. B. A. Houssay recently lectured before the Argentine Society of Biology. He reported results of experiments which were carried on with the collaboration of Drs. O. Orias and J. C. Sara. The intravenous injection of alloxan in a dose of 100 mg. for each kilogram of body weight produces early glycemia, which equals that which follows the removal of the adrenals or the section of the great and lesser splanchnic nerves. Glycemia does not increase, however, if the animals are deprived of the liver. Early hyperglycemia is followed by lowered glycemia, which lasts for several hours. It also occurs in dogs recently deprived of the pancreas, but it does not occur in diabetic dogs. Terminal hyperglycemia occurs. It shows degeneration of the islands of Langerhans. Early hyperglycemia is higher than that which follows total renewal of the pancreas. Twenty-four hours after administration of the injection of alloxan the pancreas of 5 of every 6 dogs does not secrete insulin. The adrenal incapacity persists even in the period of transient hypoglycemia. The liver seems to play the main role in the changes of glycemia, namely an early phase of hyperglycemia, an intermediate phase of hypoglycemia and a final phase of hyperglycemia.

Potassium Thiocyanate in Arterial Hypertension

In a paper read before the Ateneo del Hospital Militar Central of Buenos Aires Drs. Ernesto A. Rottjer and Alfredo C. Carreras reported good results from the administration of sodium thiocyanate in 9 cases of essential hypertension and 1 case of malignant hypertension due to diffuse postglomerulonephritis. There was a remission of symptoms in all cases. Arterial tension returned to normal in all cases. Toxic symptoms did not appear. The administration of sodium thiocyanate calls for a careful clinical examination of the patient before administering the treatment. In the course of the treatment determinations of the amount of the drug in the blood should be made twice a week. Repeated clinical examinations of the patient and determinations of the arterial blood pressure should be performed.

Dental Care of Children

Dental care for children of school age and adolescence is obligatory in Argentina. Children on entering school have a dental examination, the results of which are recorded on the proper card and the latter is kept on file. The examinations are repeated periodically. The parents are notified when the children require dental care, which can be given by the family dentist or free in the dental national centers. Parents who break the law are fined 20 to 50 Argentine pesos (\$5 to \$12). Teachers may be penalized with a fine of 100 Argentine pesos (\$25). Repeated infraction is punished with temporary closure of the school if private or with discharge of the teacher if the school is operated by the government.

Measures to Increase Birth Rate

The Minister of Internal Affairs recently appointed a committee with Dr. Manuel A. Viera as president to study and remedy the causes of the lowering of the birth rate and to stimulate the creation of large families in the country. Several problems concerned with the welfare of children will be studied. Special care is to be given to improve the economic conditions of parents of large families in order to provide the children with the proper housing, food, hygiene and cultural conditions.

Congress of Internal Medicine

The second reunion of the Society of Internal Medicine of the Asociación Médica Argentina was held during the last week of October 1944. Dr. Egidio S. Mazzei was the president. The official topic was chemotherapy (sulfonamides and penicillin) in infections in internal medicine. Dr. Mario Soto spoke on pharmacology of sulfonamides. Drs. Mariano R. Castex and Eduardo L. Capdehourat spoke on sulfonamide therapy in chronic infections of the respiratory tract. Dr. Egidio S. Mazzei spoke on sulfonamide therapy in endocarditis lenta. Drs. Paul D. White, Marion W. Mathews and Elwyn Evans reported the results of sulfonamide therapy in 85 cases of subacute bacterial endocarditis in the Massachusetts General Hospital during the years 1939 to 1944. Drs. Julio Palacio, Francisco Arrillaga, Nicolás Romano, Rodolfo A. Eyherabide, Victorio Monteverde, Diego Taylor Gorostiaga, Alberto Maggi, Carlos Alberto Videla and Guido Costa Bertani discussed the therapeutic uses of sulfonamide. Dr. Felipe Morán Miranda spoke on renal complications of sulfonamide therapy. Dr. B. Varela Fuentes of Montevideo spoke on sulfonamide therapy in biliary infections.

Control of Publicity on Cancer

A law was recently passed according to which all reports of the use of drugs or treatments for curing cancer should be made to the National Department of Public Health before being made public. The law was based on the harm which may result to the laymen in neglecting cancer for a useless treatment. The authorities of public health all through the country have given radio lectures discussing the scientific treatment of cancer and advising people to stay away from charlatans.

Professional Theses

The council of the Faculty of Medicine of Buenos Aires recently resolved that physicians graduated from the medical school can practice either with a certificate in which it is stated that they have successfully completed the studies of the curriculum and done the necessary duties, or with an M.D. diploma. The diploma is given only to students who successfully complete the studies of the curriculum and who present a "thesis of doctor in medicine" with results of scientific research as carried on during the studies in the medical school.

New Department of Public Health

The Section of Rheumatology, Cardiovascular Diseases and Neoplasms, a branch of the Division of Social Diseases, which is a department of the National Department of Public Health, was recently created. The Division of Social Diseases includes sections on cancer, leprology, venerology, mental diseases and toxicomania, rehabilitation of invalids and rheumatology, and cardiovascular diseases and neoplasms.

Marriages

DAVID M. SWITZER JR., North Little Rock, Ark., to Miss Mary Dorothy Walker of Meridian, Miss., June 3.

ALLEN MANSFIELD COLLINGSWORTH, Atlanta, to Mrs. Janice Fuquay Byers of Montgomery, Ala., July 14.

JOSEPH BRISBANE to Miss Marguerite Krock, both of New York, in Greenwich, Conn., March 10.

WILLIAM A. BUTCHER, Adrian, Mo., to Miss Elaine Carolyn Bottomley of Philadelphia, May 12.

LINDSAY KERR BISHOP, Nashville, Tenn., to Miss Marianne Coleman of Maryville, July 17.

DAVID MENDELL, Houston, Texas, to Miss Miriam Wydra of Washington, D. C., June 27.

MARK G. RISSE, Emerald, Pa., to Miss Mary Alice Christman of Allentown, June 16.

Deaths

Lewis Alexander Golden † New Orleans; University of Michigan Medical School, Ann Arbor, 1929; born in Riga, Baltic State, Dec. 31, 1903; assistant professor of neuropsychiatry at the Tulane University of Louisiana School of Medicine; served as teaching assistant in medicine, research fellow in medicine and instructor in medicine at the Tufts College Medical School in Boston; served a rotating internship at the Hillman Hospital in Birmingham, Ala., and a residency in medicine at the Boston Dispensary, where he had been assistant physician in the medical clinic and assistant physician in the nervous and mental department; formerly assistant physician at the Diagnostic Hospital, New England Medical Center; for six months clinical clerk at the National Hospital for Nervous Diseases in London, England; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the state board of institutions; member of the Southern Psychiatric Association and the American Psychiatric Association; served as secretary-treasurer of the New Orleans Society of Neurology and Psychiatry; at one time graduate assistant (teaching), neurologic department, Massachusetts General Hospital and Harvard Medical School in Boston; on the staffs of the Ochsner Clinic, De Paul Sanitarium, Charity Hospital and the Touro Infirmary, where he died June 22, aged 41, of renal lithiasis and uremia.

George Argale Harrop † Princeton, N. J.; Johns Hopkins University School of Medicine, Baltimore, 1916; born in Peru, Ill., in 1890; vice president of E. R. Squibb & Sons and director of the Squibb Institute for Medical Research in New Brunswick; at one time an intern and assistant resident physician at Johns Hopkins Hospital; for a time served on the faculty of Columbia University and the Peiping Union Medical College in China; from 1925 to 1938 associate professor of medicine at his alma mater, where he had been in charge of the chemical laboratory and work on diseases of metabolism and endocrinology; specialist certified by the American Board of Internal Medicine; fellow of the American Scandinavian Foundation and the American College of Physicians; member of the Association of American Physicians, American Society for Clinical Investigation, American Society of Biological Chemists, Society for Experimental Biology and Medicine, Société Biologique de Paris, New York Academy of Medicine and the American Clinical and Climatological Association; author of "Management of Diabetes" 1925 and "Diet in Disease" 1930; died in the Stephen V. Harkness Pavilion for Private Patients, Medical Center, New York, August 4, aged 54.

Thomas J. Williams † Chicago; State University of Iowa College of Medicine, Iowa City, 1908; born in Colwyn Bay, Wales, May 8, 1882; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; licentiate and fellow of the Royal College of Surgeons of Edinburgh, Scotland, in 1914; at one time health officer of Hiteman, Iowa; formerly professor of ophthalmology at the Illinois Post-Graduate Medical School; at the beginning of World War I was with the British Hospital Service, becoming a captain in the medical corps of the U. S. Army when the United States entered the war; on the consulting staff in eye, ear, nose and throat of the Illinois Masonic Hospital; attending surgeon to St. Francis and Evanston hospitals, both in Evanston, Ill.; died at his home in Evanston, Ill., August 10, aged 63, of coronary thrombosis.

John Cameron McCluer † Alexandria, Va.; University of Virginia Department of Medicine, Charlottesville, 1932; interned at the De Paul Hospital in St. Louis and the Camden-Clark Memorial Hospital in Parkersburg, W. Va.; past president of the Alexandria Medical Society; member and director of the city tuberculosis association, serving as a member of its board of trustees and medical advisory staff; for five years a member and for two years president of the city board of health; member and past president of the staff of the Alexandria Hospital; on the courtesy staffs of the Doctors Hospital, Emergency Hospital and the Garfield Memorial Hospital, Washington, D. C., where he died June 29, aged 39, of lymphoid pneumonia.

Louise Lockwood Culver, Sandwich, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; died July 14, aged 75, of chronic myocarditis.

Clark Bradshaw Denny † Oakdale, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1911; died in the Mercy Hospital, Pittsburgh, April 27, aged 65, of pneumonia.

Martin Icove Green † San Francisco; College of Physicians and Surgeons of San Francisco, 1921; member of the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; co-founder and chief of staff, Greens' Eye Hospital; died in the Mount Zion Hospital June 30, aged 46, of endothelial sarcoma.

Louis Benjamin Heimer, Philadelphia; University of the South Medical Department, Sewanee, Tenn., 1904; Jefferson Medical College of Philadelphia, 1905; formerly affiliated with the Northwestern General and American Stomach hospitals; died June 22, aged 65, of cerebral embolism.

Lewis George Hildreth, Marlboro, N. H.; Kentucky School of Medicine, Louisville, 1892; member of the American Medical Association; school physician and health officer; died in Keene June 25, aged 77, of arteriosclerosis, diabetes mellitus and uremia.

Wesley J. Irvine, Manawa, Wis.; University of Maryland School of Medicine, Baltimore, 1892; member of the American Medical Association; honorary member of Waupaca County Medical Society; member of assembly, state legislature, from 1905 to 1907; served during World War I; president of the Farmers State Bank of Manawa; died June 6, aged 78, of cerebral thrombosis.

Archibald Charles Kappel † Franklin, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1913; member of the city council; died June 4, aged 56, of heart disease.

Daniel Kessler, Weston, W. Va.; University of Louisville Medical Department, Louisville, Ky., 1891; member of the American Medical Association; honorary member of the West Virginia State Medical Association; one of the founders of Camp Gauley in Webster County; died July 30, aged 81, of heart disease.

Reinoehl Knipe, Norristown, Pa.; Medico-Chirurgical College of Philadelphia, 1898; member of the American Medical Association; served as chief of the state tuberculosis clinic; for many years chief physician for the Montgomery County prison; on the staffs of the Montgomery and Sacred Heart hospitals; died June 21, aged 77, of heart disease.

Frank Xavier Koltes † Medical Director, Captain, U. S. Navy, retired, Milwaukee; Rush Medical College, Chicago, 1903; entered the medical corps of the U. S. Navy as a lieutenant (jg) on May 21, 1907; became a captain on May 11, 1930; retired April 1, 1938 for incapacity resulting from an incident of service; fellow of the American College of Surgeons; died in the U. S. Naval Hospital, San Diego, July 14, 1944, aged 66, of coronary heart disease.

Elmer Lee, New York; Missouri Medical College, St. Louis, 1882; died in the Cincinnati Sanitarium, Cincinnati, June 13, aged 89, of generalized arteriosclerosis and senility.

Joseph Leo, New York; University and Bellevue Hospital Medical College, New York, 1910; died June 28, aged 65, of heart disease.

Fred Irvin Longstreet, Montville, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1899; died in the All Souls Hospital, Morristown, June 14, aged 69, of peritonitis from ruptured diverticulum of the colon.

Inte Ignaz Lourie, Brooklyn; Long Island College Hospital, Brooklyn, 1904; also a pharmacist; formerly affiliated with the Post-Graduate, Trinity and Israel Zion hospitals; died in the Long Island College Hospital June 21, aged 69, of heart disease.

Albert Emanuel Loyer, New Washington, Ohio; Medical College of Ohio, Cincinnati, 1895; served as surgeon to the Lake Erie and Western Railroad; died June 25, aged 72, of cerebral hemorrhage and hemiplegia.

John Neal Martin † Unionville, Mo.; Chicago College of Medicine and Surgery, 1916; served as county health officer; died June 10, aged 52, of injuries received in an automobile accident.

James Claude McLallen, Cicero, Ill.; Jenner Medical College, Chicago, 1909; died in St. Elizabeth's Hospital, Chicago, June 14, aged 67, of coronary thrombosis.

Walter Guy McLeod † Southern Pines, N. C.; Baylor University College of Medicine, Dallas, Texas, 1921; interned at the Baylor Hospital in Dallas and the St. Francis Hospital in Jersey City, N. J.; died in the Mountain Sanitarium and Hospital, Fletcher, June 23, aged 54, of myocardial insufficiency.

Beriah Alembert Montgomery † Grove City, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; served during World War I; major, medical reserve corps, U. S. Army, not on active duty for eighteen years.

member of the board of education; served on the staff of the Grove City Hospital, where he died July 21, aged 72, of coronary thrombosis.

Watson Alexander Moore, Cleveland, Mo.; Medical-Chirurgical College of Kansas City, Mo., 1904; member of the American Medical Association; served as president of the board of education and as postmaster of West Line; for many years member of the board of education in Cleveland; died in Kansas City June 14, aged 66, of generalized arteriosclerosis and coronary thrombosis.

Benjamin M. Nicholson, Enfield, N. C.; University College of Medicine, Richmond, 1910; member of the American Medical Association; honorary member of the Medical Society of the State of North Carolina; died in the Rocky Mount Sanitarium, Rocky Mount, June 11, aged 56, of cardiovascular renal disease.

Charles Julius Oppenheim • Forest Hills, N. Y.; Cornell University Medical College, New York, 1923; served on the staffs of the Beekman and Lenox Hill hospitals, New York; died June 24, aged 50, of hypertension and arteriosclerosis.

Ralph V. Overton • Winner, S. D.; Lincoln (Neb.) Medical College of Cotner University, 1902; part owner of the Winner General Hospital; died in Sioux City, Iowa, June 20, aged 65, of coronary thrombosis and hypertensive heart disease.

William B. Page, Goshen, Ind.; Hering Medical College, Chicago, 1896; formerly a medical missionary in India; served during World War I; past president of the Elkhart County Medical Society; died June 14, aged 74, of coronary thrombosis.

Charles Walter Patterson, Crowder, Miss.; Mississippi Medical College, Meridian, 1907; died in Grenada June 22, aged 70, of cerebral hemorrhage.

Ira E. Perry • North Manchester, Ind.; Medical College of Indiana, Indianapolis, 1905; served as councilor of the Eleventh District Medical Society; for many years health officer of Wabash County; at one time county coroner; past president of the Wabash County Medical Society; died June 18 at his summer home on Webster Lake, aged 72, of heart disease.

Peter Heije Poppens • Princeton, Ill.; Rush Medical College, Chicago, 1920; past president of the Bureau County Medical Society; on the staff of the Julia Rackley Perry Memorial Hospital; interned at the Presbyterian Hospital in Chicago; died June 8, aged 53, of embolism as the result of an automobile accident.

Frank Edward Potter, Middletown, Conn.; College of Physicians and Surgeons, New York, 1889; member of the American Medical Association; died in East Hampton May 23, aged 90, of coronary thrombosis.

LIEUT. COMDR. CLYDE H. BROWN
(MC), U.S.N.R., 1902-1945

CAPT. DUANE HAROLD CALLISTER
M. C., A. U. S., 1913-1945

LIEUT. JAMES ALBERT GAFFORD JR.
(MC), U.S.N.R., 1906-1945

Theodore Herbert Page, Peoria, Ill.; Rush Medical College, Chicago, 1897; served overseas during World War I; died in Tucson, Ariz., June 11, aged 70, of carcinoma of the colon.

Henry G. Reemsnyder, Ephrata, Pa.; Jefferson Medical College of Philadelphia, 1881; member of the American Medical Association; at one time member of the board of health; died in St. Joseph's Hospital, Lancaster, May 21, aged 84, of

KILLED IN ACTION

Clyde Hulee Brown • Cullman, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1926; interned at the Knickerbocker Hospital in New York; member of the Medical Society of the State of New York; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on May 12, 1942; assigned to the Naval Hospital in Newport, R. I.; in command of a Marine Corps Mobile Hospital unit; died in Okinawa April 12, aged 42, of fragment bomb wound of the head.

Duane Harold Callister, Fillmore, Utah; Rush Medical College, Chicago, 1942; interned at the Dr. W. H. Groves Latter-Day Saints Hospital in Salt Lake City; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 24, 1943;

later promoted to captain; killed in action in Belgium January 9, aged 31.

James Albert Gafford Jr. • Huntington Park, Calif.; Stanford University School of Medicine, San Francisco, 1931; fellow of the American College of Surgeons; interned at the Los Angeles County General Hospital, where he served a residency and had been junior attending gynecologist; served as instructor in obstetrics and gynecology at the University of Southern California School of Medicine; member of the staff of the Methodist Hospital of Southern California, Los Angeles; began active duty as a lieutenant in the medical corps, U. S. Naval Reserve, on Feb. 15, 1943; assigned to Camp Pendleton in Oceanside; since January 2 junior medical officer on the U. S. S. *Birmingham*; died in the Pacific area May 4, aged 33, of extreme multiple injuries.

hypertensive arteriosclerotic heart disease and chronic glomerular nephritis.

Carl Eugene Richardson * Franklin, Mass.; Tufts College Medical School, Boston, 1907; medical examiner in Norfolk County for twenty-one years; member of the school board; trustee of the Benjamin Franklin Savings Bank; died July 30, aged 61, of coronary thrombosis.

William R. Riley, Everton, Mo.; St. Louis College of Physicians and Surgeons, 1897; chairman of the Dade County Central Democratic Committee; for many years president of the board of education; served on the staffs of the Burge Hospital, Springfield Baptist Hospital and St. John's Hospital, Springfield, where he died May 15, aged 77, of heart disease.

Leroy L. Sawyer, Greatbridge, Va.; University of Maryland School of Medicine, Baltimore, 1890; a director of the Merchants and Planters Bank in Norfolk; died June 13, aged 80, of pneumonia and heart disease.

Albert F. Schwenke, Lancaster, Ohio; Starling Medical College, Columbus, 1889; died June 2, aged 80, of heart disease and arteriosclerosis.

Charles James Search, Brooklyn; University of Wooster Medical Department, Cleveland, 1892; member of the American Medical Association and the American Roentgen Ray Society; at one time instructor in physiology at the Long Island College

Myron Herbert Simmons, Oak Hill, N. Y.; Albany Medical College, 1880; served as president and member of Orange Memorial Hospital Dispensary staff in Orange, N. J.; in 1944 received a gold decoration from the alumni association of Albany Medical College in recognition of his fifty years of meritorious service to humanity; died July 16, aged 87, of congestive heart failure.

Tilden H. Singleton, Bowling Green, Ky.; Hospital College of Medicine, Louisville, 1904; member of the American Medical Association; member of the county board of health; on the staff of the City Hospital; died June 6, aged 68, of coronary thrombosis.

John Yeoman Sinton * Imlaystown, N. J.; Medico-Chirurgical College of Philadelphia, 1908; for many years school physician; secretary of the Upper Freehold Township Board of Health; served on the staff of St. Francis Hospital in Trenton; died May 31, aged 81, of coronary occlusion.

Ernest William Slater, Jewell, Iowa; Northwestern University Medical School, Chicago, 1906; died May 24, aged 72, of acute dilatation of the heart.

Thomas O. Smith, Wilsonville, Ala. (licensed in Alabama in 1907); member of the American Medical Association; member of the school board and city council; died June 17, aged 69, of cerebral hemorrhage.

LIEUT. THEODORE BOYT
(MC), U.S.N.R., 1912-1944

CAPT. ARTHUR JAMES LEONARD
M. C., A. U. S., 1914-1944

LIEUT. WILLIAM ASHBY DAVIS
M. C., A. U. S., 1916-1944

Hospital; served on the staffs of St. John's Hospital and the House of St. Giles the Cripple; died June 5, aged 81, of arteriosclerosis.

Mark Shrum, Lynn, Mass.; University of Louisville (Ky.) Medical Department, 1894; at one time a member of the board of registration in medicine; died June 30, aged 76, of intestinal obstruction.

Robert Edward Whitehead * Kempsville, Va.; Medical College of Virginia, Richmond, 1897; served as president of the Princess Anne County Medical Society and as councilor of the Second District of the Medical Society of Virginia; member of the Seaboard Medical Society; member of the county draft board during World Wars I and II; died in a hospital at Norfolk July 2, aged 72, of cerebral hemorrhage.

KILLED IN ACTION

Theodore Boyt, South Amboy, N. J.; Long Island College of Medicine, Brooklyn, 1939; served an internship at the Jersey City Hospital in Jersey City and later became resident physician at the Woman's Hospital in Detroit; commissioned a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on June 5, 1942; promoted to lieutenant on May 1, 1943; following service and special training in this country, assigned to the destroyer U. S. S. *Buck*; participated in the Sicilian invasion and received the European-African-Middle Eastern Area campaign ribbons and the Purple Heart; while on an anti-submarine patrol south of the Isle of Capri the *Buck* was torpedoed and sunk; at first reported missing in action; aged 32; presumptive date of death Oct. 10, 1944.

Arthur James Leonard, Pittsburgh; University of Pittsburgh School of Medicine, 1941; interned at the Allegheny General Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 1, 1942; promoted to captain; served in the First Division; served through the African and Sicilian campaigns; killed in action in France July 3, 1944, aged 29.

William Ashby Davis, Agricola, Va.; University of Virginia Department of Medicine, Charlottesville, 1942; interned at the Roper Hospital in Charleston, S. C.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 16, 1943; killed in action in North African area April 20, 1944, aged 27.

Bureau of Investigation

NEW NAMES FOR OLD SWINDLES

Mail-Order Defrauders Are Also Repeaters

Fraud orders issued by the United States Post Office are really effective—so far as the trade styles and names used at the time of the order are concerned. Circumvention therefore requires the use of new trade styles and names—but this fortunately results in the issuance of supplemental orders by the Post Office Department as indicated in the following paragraphs:

More Edward S. Hidden Frauds.—In this department of *THE JOURNAL* Dec. 20, 1941, page 2188, there appeared under the title "Edward S. Hidden and Some Fakes" a detailed account of fraud orders that had been issued by the Post Office Department against two earlier swindles perpetrated by Hidden. One was a "fat cure" variously known as "Slim-A-Lax" and "Tab Thins." This business he operated under the names Madison Chemical Company, Tab Thins Company, Slim-A-Lax Company, Riverside Chemical Company and C. N. Talcott. The other was an alleged baldness cure called "Nuhair," in the sale of which he did business under his own name and also as C. J. Walton, Nuhair Company and Nu Hair Company. Like some others who were denied the use of the mails by the Post Office Department, Hidden stayed in business simply by dropping his original trade styles and adopting new ones. He appears to have organized the Cooper Distributing Company and the Carolina Chemical Company, both of Charleston, S. C. Under the latter title there were also branches at Pitcairn and Pittsburgh, Pa., Detroit, Quincy, Ill., and Greensboro, N. C. Under these various trade styles Hidden promoted "Nu-Hair" for growing hair, with an accessory "slicking" cream, besides "Lax," a laxative mixture for reducing, and "Muscl-Free," a liniment to be used in connection with certain powders for various forms of rheumatism. Again Hidden was ordered by the Post Office Department to show cause why he should not be debarred from the mails for obtaining money through those channels by means of false and fraudulent pretenses, representations and promises. At the hearing a government chemist testified that Nu-Hair was a hydro-alcoholic liquid containing 10 per cent of mineral oil by volume and 9.5 per cent of isopropyl alcohol, colored pink; that the Lax treatment consisted of some pink tablets composed of laxatives, and some white ones, each apparently containing about ½ grain of thyroid; and that Muscl-Free consisted of a bottle of liniment for external use and some powders to be taken internally. The witness testified that he had found the liniment to contain the ingredients declared on the label, namely, isopropyl alcohol and methyl salicylate, but that his findings as to the composition of the powders (acetylsalicylic acid, sodium salicylate and milk sugar) differed from that declared on the label, which listed caffeine and calcium salicylate in addition. An expert medical witness for the government testified at some length regarding the worthlessness of these "cures," and on Sept. 4, 1944, a fraud order was issued against Edward S. Hidden, the Cooper Distributing Company, Carolina Chemical Company, and the branches of the latter in the various cities mentioned. On the same date another fraud order was issued against the Lax Company, Reducing Specialists; D. Rodriguez, Weight Consultant, and the Charleston Vitamin Company, under which names Hidden was operating his scheme from Mexico City. By the order Hidden was denied further use of the United States mails. As might be expected, he began to operate from another Mexican city, Nuevo Laredo, under one of the trade styles he had used in the foregoing scheme, Lax Company. A month later—on Oct. 3, 1944—the Post Office Department issued a fraud order also against this name, but it is a sporting proposition that ere long he will be heard from again in Mexico, with the same old stock in trade but a new title and address.

Trans-Continental Products.—This was a follow-up of another mail-order swindle, which originated in Chicago with one Eli Siegel, M.D., and which he promoted under such names as Chicago Medical Institute, Dr. Siegel's Medical Products, Chicago Medical Offices and Globe Surgical Institute. Dr. Siegel holds a diploma from a medical school of questionable standing. In *The Journal*, Jan. 22, 1938, page 303, appeared a long account of the case in which the Post Office Department in 1937 issued a fraud order against Siegel personally, and his concern "Dr. Siegel Medical Products." As the article stated, he had appealed to sexual neuroasthenics by offering certain drugs and appliances that he claimed would make them "full of vim, vigor and vitality" and cause them to "feel thirty years younger." He called his drug combinations "Revivo" and "Control-O" and his appliance the "Great Mechanical Developer," which device the government declared was merely a mechanical masturbator. On Aug. 28, 1940, on application of Dr. Siegel and what appeared to be evidence that he had abandoned his mail-order scheme, the fraud order was revoked to the extent of permitting him to receive mail addressed personally to him. Later, however, another enterprise was launched by Siegel's wife, under the names U. S. M. Products, U. S. M. Products Company, U. S. Medical Products, and U. S. Medical Products Company, Chicago, to sell two nostrums through the mails. These were "Firm-X," to restore "pep" to all men over forty years old, overcome all symptoms of old age and enable users to maintain their youthful vigor, energy and vitality; and "Stop-X," represented to overcome all kidney and bladder weaknesses. When a new Post Office

fraud order threatened, Mrs. Siegel attempted to circumvent it by filing an affidavit that the scheme had been discontinued and that the Chicago postmaster was to return to writers any mail addressed to her concern, with the stamped notation "Out of business." Soon afterward, however, the Post Office Department learned that she was again using the mails in a questionable manner, this time using the name Trans-Continental Products, and accordingly the Department directed her to show cause why a fraud order should not be issued against that name. At the hearing of the case it was brought out that Mrs. Siegel was now calling her products "Peps Regular," "Peps Special" and "Peps for Women" or "Pepson" and promoting them for lost sexual power in men and women, sending out literature similar to that used by Dr. Siegel in the earlier enterprise. An expert medical witness for the Post Office Department testified that in view of the composition of the nostrums as reported by a government chemist, they did not fulfil the claims made for them. The business was therefore judged a scheme for obtaining money, through the mails by means of false and fraudulent pretenses, representations and promises, and since investigation had shown that the apparently fictitious name John Dreyer had been employed in operating the business, a fraud order was issued Sept. 11, 1944, against John Dreyer, the Trans-Continental Products, and their officers and agents, debarring them from further use of the mails.

Correspondence

GAMMA GLOBULINS

To the Editor:—In a communication (July 7, p. 750) an editorial of *THE JOURNAL* (June 9, p. 442) was criticized for giving "the impression that only until recently has the origin of the globulins remained uncertain." According to Dr. Hobart A. Reimann, numerous investigators in the last fifty-three years have held the view that globulins originated in the leukocytes.

We wish to point out that the literature referred to by Dr. Reimann (Reimann, H. A.; Medes, G., and Fisher, L.: *The Origin of Blood Proteins, Folia haemat.* 52:187, 1934) is not concerned with gamma globulins; it deals almost entirely with fibrinogen, which is now generally believed to be formed in the liver. Only two authors are quoted to have suggested that some globulins as well as fibrinogen were possibly produced by leukocytes, while one author believed that all plasma proteins arose from the disintegration of leukocytes and possibly also from the platelets and other cells in contact with the blood. When studying this problem experimentally in rabbits, Reimann and his associates were unable to find "decisive evidence to support the leukocytic origin of blood proteins or that the bone marrow is the chief site of their origin." When examining the cells of experimental pleural exudates they found "that certain substances in the leukocyte extracts were salted-out at various concentrations of Na₂SO₄, which are known to throw down various protein fractions." They admitted that this observation was not sufficient to "identify these substances with certainty," as they failed to give the usual immunologic and clotting reactions. Reimann and his associates came to the conclusion that "thus far, therefore, it is impossible to designate either the liver or other hemopoietic organs, the leukocytes or the erythrocytes as the chief or sole sources of fibrinogen."

Dr. Reimann's communication, therefore, does not reflect on the validity of the various recent editorials of *THE JOURNAL* on the production of antibodies and other gamma globulins. It seems that our own observations (Ehrich, W. E., and Harris, T. N.: *J. Exper. Med.* 76:335 [Oct.] 1942. Harris, T. N.; Grimm, E.; Mertens, E., and Ehrich, W. E., *ibid.* 81:73 [Jan.] 1945) as well as those of White and Dougherty (Dougherty, T. F.; Chase, J. H., and White, A.: *Proc. Soc. Exper. Biol. & Med.* 57:295 [Nov.] 1944. White, A., and Dougherty, T. F.: *Endocrinology* 36:207 [March] 1945) and of Edward H. Kass (*Science* 101:337 [March 30] 1945) are the only ones which indicate that antibodies and other gamma globulins may be formed by the lymphocytes.

WILLIAM E. EHRLICH, M.D.

VESICULOPUSTULAR ECZEMA

To the Editor:—Probably two thirds of the patients seen on dispensary service in the field are suffering from some type of skin disease. It is important to recognize and treat these cases early, for secondary infection occurs readily in the tropics as a result of the humidity and lack of bathing facilities noted among the front line outfits.

During the past two years I have had the opportunity to observe a considerable number of cases of vesiculopustular eczema. There is no conclusive evidence that micro-organisms act as a primary cause, but they frequently aggravate the condition as secondary invaders. The lesions usually present themselves as small maculopapular eruptions, located usually in the axillary regions, the thorax and the anterior and anterolateral abdominal walls. These lesions cause mild pruritus associated with a "burning sensation" when the lesions are found in the axillas. After several days the small macular areas become prominent as larger vesicles filled with a clear fluid. Unless the lesion is treated at this stage the vesicles become pustular in nature.

In the macular stage the treatment is purely symptomatic, calamine lotion being used on the body surfaces and zinc oxide applied to the lesions in the axillas. As soon as the lesions become vesicular the vesicle should be removed and touched with a small amount of Dalibour's solution (copper sulfate, zinc sulfate and gentian violet). The astringent action of the latter quickly forms a thin film over the lesion, and desquamation occurs, usually leaving an area of depigmentation. The pruritus and slight pain caused by the lesion is relieved immediately on first application. No fungi or bacteria were found in the vesicular lesions, and when the latter became pustular, staphylococci and streptococci were the predominant organisms found.

I mention this type of treatment mainly because of the rapidity of cure obtained, and hence there is less chance of overtreatment, which so often occurs in treating diseases of the skin.

P. M., San Francisco, California.

PNEUMONIA AND RESPIRATORY DISEASE
WITH A POSITIVE WASSERMANN TEST

To the Editor:—In the abstract from the article in *Medicine* (23:359 [Dec.] 1944) by Davies in *THE JOURNAL*, February 24, page 489, on false positive serologic tests for syphilis, Davies mentions the possibility of positive tests of this kind for certain types of atypical pneumonia. Moreover McNeil in the *American Journal of the Medical Sciences* (209:48 [Jan.] 1945) mentions his observations of atypical cases of pneumonia with strongly positive Kahn tests. Will you allow me in this connection to refer to a paper published in the *Helvetica medica acta* (7:497 [March] 1941) which may have escaped the notice of the authors, probably because of difficulties of communication caused by the war. After the observation of some sporadic cases by Lindau and Fanconi, I was able at that date to report 9 endemic and 10 additional sporadic cases and to show that one can speak of a nosologic entity with a characteristic symptomatology. I named the disease pneumonia with positive Wassermann test. Since that time it has been possible to supplement the symptomatology with more than 50 further observations (Gsell, Steinmann, Rossier, Pfisterer).

In most cases the disease shows a remarkably torpid course. Generally the temperature reaches only subfebrile values; high fever is found but rarely, whereas cases without any rise of temperature have been observed. Characteristic physical signs

are those of a bronchitis such as dry and moist rales combined with signs of circumscribed consolidation. This can be important as a means of distinction from other atypical forms of pneumonia. The sedimentation rate of the red blood corpuscles is generally considerably elevated. The white blood cell count is normal. The percentage of polymorphonuclear cells is not increased, but there is a shift to the left. X-ray examination shows mostly one single, rarely more than one, very mottled not very dense shadow. Every lobe of the lung can be affected. The corresponding bronchopulmonary lymph nodes are often enlarged. Months can pass before the infiltration has entirely disappeared. The serologic tests remain positive approximately as long as the signs of consolidation last, but a strict parallel cannot be drawn. The serologic reactions can be more or less strongly positive.

Some patients present symptoms of the upper part of the respiratory tract including sinusitis without definite infiltrations of the lung. Therefore one might also speak of a respiratory infection with positive Wassermann test.

The contagiousness is striking. Endemics have been found in military units and in families. Etiologically a virus can be presumed, the bacteriologic examination of the sputum giving no clear results.

As to differential diagnosis, tuberculosis and syphilis in the first place must be excluded, which, given a sufficient time of observation, presents no difficulties because of the spontaneous disappearance of the symptoms.

R. HEGGLIN,
University of Zurich,
Switzerland.

EARLY DIAGNOSIS OF KALA-AZAR

To the Editor:—I was greatly interested to read the report of a case of kala-azar in an Italian prisoner by Colonel Sweeney, Major Friedlander and Lieutenant Colonel Queen in *THE JOURNAL* for August 4. The authors are to be congratulated on an excellent case study, but it seems unfortunate that the diagnosis was not made earlier and that splenectomy was necessary to make the diagnosis. This is undoubtedly due to the fact that physicians in the United States and medical officers in the armed forces are generally unfamiliar with this disease, which is not endemic in this country.

Since a number of cases of kala-azar have occurred in our armed forces, and since, because the incubation period may be as long as fifteen months, some symptoms are likely to develop even after discharge to civilian life, I should like to call attention to a few points which may assist in earlier diagnosis and thus be an aid both to the physician and to the patient.

Kala-azar should be suspected as the first probability, instead of the last, in any person who has been in one of the three great endemic areas and who presents a clinical picture of spiking daily fever, malaise and leukopenia. The three great endemic areas are the Mediterranean area, northeastern India and China north of the Yangtze River. The fever often, although not always, shows more than one spike of rise in twenty-four hours. The spleen may not be palpable until two months after the onset of symptoms. There may be no anemia, no abnormal rise of blood globulin, no prolongation of bleeding time or coagulation time, and the serum aldehyde test may be negative. Parasites cannot be found in the circulating blood. Malaria can be easily excluded by careful blood examination, and typhoid can be excluded by the usual tests.

The only method of making an early diagnosis is to find the Leishman-Donovan bodies in puncture material from the organs which become most heavily infected. Bone marrow puncture should be performed first, an attempt being made to obtain marrow tissue with as little blood as possible.

Parasites are often scarce in this material, but careful examination of Giemsa stained smears, referred to an expert labor-

tory, will often make the diagnosis. Culture of bone marrow material on NNN medium at room temperature, according to the technic in textbooks of tropical medicine or parasitology, will often produce demonstration of the flagellate forms within a week or two.

The liver is more likely to show parasites than the bone marrow, and liver puncture through one of the lower intercostal spaces, if properly performed, is practically without danger. The same general technic as for spleen puncture should be employed. The principal precaution is to make certain that the blood coagulation and bleeding times are within normal limits. If they are increased a blood transfusion will reduce them to normal.

Spleen puncture should not be attempted unless the spleen protrudes an inch or more below the costal margin.

I believe that if this disease is kept in mind by all physicians, and if proper diagnostic procedures are carried out before all the possible examinations for every other disease are conducted, diagnoses will be made much earlier than has been the case in the past.

HENRY E. MELENEY, M.D., New York.

ADMINISTRATION OF AMINO ACID DIGEST

To the Editor:—In the note "Fatality Associated with the Administration of Amino Acid Digest" by Curreri, Hibma and Cohen (*THE JOURNAL*, July 7) it is stated that "to our knowledge, no mortality has been previously recorded with the use of amino acids."

I wish to call attention to the paper by Hopps and Campbell, "Immunologic and Toxic Properties of Casein Digest as Prepared for Parenteral Administration" (*J. Lab. & Clin. Med.* 28:1203 [July] 1943), in which is reported a death one hour after the administration of 200 cc. of 10 per cent amino acid solution (hydrolyzed casein). At necropsy it was determined that this patient had severe hepatic damage. The mechanism of this untoward reaction to amino acids was discussed and it was concluded that in patients with severe hepatic damage (e. g. acute toxic necrosis or diffuse hepatitis) parenteral therapy with amino acids might result in sudden death.

In the case reported by Curreri, Hibma and Cohen it is stated that "the liver showed slender hepatic cells, hepatitis and infiltration of portal canals with lymphocytes and occasional polymorphonuclear cells." This case would seem to confirm our previous observation and introduce an important contraindication to the parenteral administration of amino acids.

HOWARD C. HOPPS, M.D., Oklahoma City.

Professor of Pathology, University of
Oklahoma School of Medicine.

"WHOLE" OR "CITRATED" BLOOD

To the Editor:—Dr. Lewisohn maintains that the term "whole" blood, as suggested by Dr. Scannel, should include "citrated" blood. I respect the opinions of both of these men.

We have been using primarily "citrated" blood for twenty-three years in our obstetric service. I've always differentiated between "citrated" blood and "whole" blood because even though we have used adequate amounts of "citrated" blood, we have, during this period of time, had some 8 or 10 patients who continued to bleed from incisions. This bleeding was promptly stopped by the injection of 400 to 500 cc. of blood without any anticoagulant, the transfer being made by the multiple syringe method. The incidence of reaction has been slightly higher with citrated than with whole blood, but in neither instance have they been of great significance.

WILLIAM J. DIECKMANN, M.D., Chicago.

Chief of Staff, the Chicago Lying-In Hospital.

Society Proceedings

WAR WOUNDS OF THE SPINAL CORD

A Special Session, held at the Newton D. Baker Hospital, Martinsburg, W. Va., June 20, 1945

Foreword

BRIGADIER GENERAL FRED W. RANKIN, Chief Consultant in Surgery, U. S. Army: The highly effective manner in which the Medical Department of the U. S. Army is caring for and rehabilitating casualties who have suffered war wounds of the spinal cord represents one of the major medical achievements of this war. The gratifying results which have been and continue to be attained have been made possible by early surgical intervention following wounding in all cases in which there is the slightest doubt that the cord has been damaged, by as prompt evacuation to general hospitals in the United States as is compatible with the safety of the patients, and by the concentration of these cases in nineteen of the general hospitals of the United States where facilities for their specialized treatment have been provided and well organized programs for their convalescent care and rehabilitation have been developed. The high degree of integration and coordination which has characterized the efforts of surgical and medical specialists, nursing personnel, enlisted attendants, physical therapists, dietitians, occupational therapists and Red Cross workers has produced in these nineteen general hospitals a program of therapy, convalescent care and rehabilitation which in quality and effectiveness far surpasses that ever before afforded paraplegic patients. The energetic and cooperative efforts on the part of the personnel concerned with this program have made a notable accomplishment in a condition that has long been considered a grave and tragic problem.

The following symposium has been prepared by a number of authors whose unique experiences with the problem of spinal cord injuries renders them capable of speaking with unusual authority on this difficult subject. The papers of this symposium deserve the careful consideration of the profession, for a defeatist attitude in the care of patients with traumatic transverse myelitis can no longer be tolerated. Rehabilitation, when properly conducted, can and must establish a wheel chair life for the majority and walking with the aid of braces or crutches for many.

The Paralyzed Patient: Neurologic Aspects

MAJOR CHARLES W. ELKINS, M. C., A. U. S.: Prior to World War II there was no unanimity of opinion as to the therapy for a patient who had received a spinal cord injury. As a result of the increase in numbers of this type of injury since the advent of the war, the attention of many individuals in the Army Medical Corps has been focused on this problem. The Army Medical Corps has initiated certain concepts and principles in therapy which will serve as a guide post in the future for the treatment of a type of injury which is bound to be more numerous as our age becomes increasingly mechanized. Treatment begins from the moment of injury and does not cease until everything possible has been done to insure a satisfactory outcome. A definition of satisfactory outcome from a neurosurgical point of view means that it must be determined that further surgery is not indicated in order to permit or to aid in recovery of function to the spinal cord in both sensory and motor spheres. The patient must be free from pain. The patient must be relieved of incapacitating spinal reflexes and paraplegia in flexion.

The cause of pain following injury to the spinal cord may be relatively simple or somewhat obscure. Retained foreign bodies in close proximity to pain tracts or posterior nerve roots may be the etiologic factor. Arachnoiditis following trauma to the spinal cord may result in pain either generalized or girdle in character. Bony overgrowth, from healed fractures, impinging on nerve roots may be responsible for pain

in certain cases. Involvement of the sympathetic nervous system may result in a most distressing type of pain.

Removal of retained foreign bodies and bony overgrowths is fundamental surgery when their presence has a reasonable chance of being the causative factor of pain. Alcohol injection of posterior nerve roots may be employed if the pain is segmental and the etiologic factors are obscure or the chances of relief by more direct methods slight. This procedure is not usually incapacitating unless employed in the low sacral region, where there is danger of interfering with bladder and bowel function. Alcohol injection into the subarachnoid space should be generally avoided because of the danger of upsetting the relationships of a bladder whose physiology is already precarious. Of the surgical procedures commonly employed, section of posterior nerve roots is the simplest and offers the best chance of success particularly in girdle type pain. Will the interruption of skin reflexes following section of certain posterior roots have deleterious effects on an autonomous bladder? If these more simple methods for relieving pain result in failure and involvement of the sympathetic nervous system has been discarded as the etiologic factor, a section of the spinothalamic tract may be employed. This is not a particularly hazardous procedure but has certain disadvantages. The tract is not on the surface of the cord and therefore the section cannot be done under direct vision. Certain pain fibers, therefore, may be left intact. Carefully performed, however, this procedure may result in relief of pain where other methods have failed. While patients of this type do not readily tolerate pain, neither do they tolerate extensive surgical procedures, and therefore following careful consideration of the cause of pain the simplest procedures available which would seem to offer the best chance of success should be employed in order to relieve this most distressing symptom. Out of a total of 69 spinal cord injuries, both complete and incomplete, as of the 1st of May, 24 had spinal reflexes, the severity varying from complete to mild incapacitation. Incapacitation must needs be defined when used in describing a symptom in a paraplegic patient. When one considers that the ultimate aim in the treatment of a paralyzed patient is some method of ambulation, it may readily be seen that automatic spinal reflexes and particularly the frequently coexisting complication of paraplegia in flexion may be considered incapacitating. A term which I have discarded but which is generally used to describe these phenomena is "mass reflexes." A mass reflex has been described as a maximal motor response in flexion to a minimal sensory stimulus in an animal with a transected spinal cord. My reasons for discarding this term are that not all of our patients with proved transections of the cord have maximal motor response to even strong sensory stimuli and indeed some do not have even minimal motor response. To continue this discrepancy further, we have observed patients with partially transected cords who demonstrate probably maximal motor response to minimal stimuli but the response is in extension and not in flexion. Thus I believe the term spinal reflex to be the more accurate term of the two. The mechanics of a simple and uncomplicated spinal reflex consists in sensory stimuli entering the spinal cord through the posterior nerve roots and, after transmission to a large number of anterior horn motor cells, emergence as efferent stimuli to motor groups. It would seem logical, therefore, that an interruption of this cycle would control spinal reflexes in the area involved, depending on where and over what extent the cycle was interrupted. This has been done on 3 patients at this hospital with success. Provided the patient is incapacitated and that all hope of spontaneous recovery has been abandoned, the procedure of anterior root rhizotomy which we have employed seems indicated.

A Plea for Exploration of Spinal Cord and Cauda Equina Injuries

LIEUTENANT COLONEL AUGUSTUS McCRAVEY, M. C., U. S. Army, Neurosurgical Section, Wakeman General Hospital, Camp Atterbury, Indiana: Such authorities as Frazier, Lyster, Mock, Oldberg, Wechsler, Love, Munro, Coleman and Meredith, Kennedy and, more recently, Sparling have advocated exploratory laminectomy. With the present advances in surgery, the operative procedure can be done with a minimum of risk to life. Thirty-two laminectomies have recently been

done at Wakeman General Hospital, under local anesthesia, without a death or postoperative complication. If a conservative policy is adopted, it is difficult to select those cases which may be helped by surgery. The neurologic examination can reveal only the degree of physiologic interruption but not the extent of the anatomic lesion. The Queckenstedt test has been eliminated as a criterion in selection of cases for laminectomy by Mayfield. Poppen and Hurxthal have demonstrated that the Queckenstedt test gives a normal response as long as the lumen of the subarachnoid space is not less than the bore of the needle used. Likewise, x-rays of the spine are not always reliable. Depressed bone fragments into the neural canal are often found at operation with a previous negative x-ray report. At Wakeman General Hospital 71 patients have been admitted with penetrating wounds of the spine with spinal cord and cauda equina injury. Thirty-six still require routine paraplegia care, of which 18 are complete paraplegias. This report will be confined to that group of 36 still requiring paraplegia care. Thirteen had adequate previous operative treatment with the time between injury and surgery varying from three hours to twenty-five days. Five have shown partial return of motor and sensory function, of which 2 were cervical, 1 dorsal and 2 cauda equina injuries. Two patients not previously operated on are awaiting surgery, which has been deferred until adequate nutrition can be established.

The remainder of the 21 patients have had adequate exploratory laminectomies. Six were explored for foreign bodies in or adjacent to the neural canal. Two were bone fragments and 4 were shell fragments. Three showed neurologic improvement. Three had severe pain which was relieved by surgery. Seven were operated on for pain only. All were cauda equina and conus lesions, of which 4 were improved, 3 were only temporarily relieved and chordotomy is contemplated for this group. Eight patients have not had previous exploratory laminectomies. In 7 the dorsal cord and in 1 the cervical cord was involved. Two incomplete lesions showed definite improvement and 1 complete lesion is now showing movement of toes. The cause for operative treatment in the group with pain and foreign bodies is obvious and results are often gratifying. Of the group not previously operated on 6 showed complete physiologic interruption by neurologic examination and 1 of these was definitely improved. This is considered significant, since this group is usually considered hopeless. Much care has been taken in selecting and preparing these cases for surgery. Emphasis has been placed on the care and treatment of urinary tract infection and decubitus ulcers. No surgery is done until all nutritional deficiencies have been corrected and there is a balanced protein metabolism. This group of patients is anxious to have any type of surgery which may offer the slightest hope and will often ask for exploratory surgery.

DISCUSSION

MAJOR GEORGE MALTBY, M. C., A. U. S.: The complication of mass reflexes and spinal reflexes can be serious. I feel that the operation of anterior rhizotomy may be at times a life saving procedure. I have done one such operation on a man with pronounced flexion contractures. They had become so severe that he had had suicidal ideas. The operation in this instance was extremely successful. His legs have straightened out and I feel that he is making gratifying improvement. Once the spasms are controlled it is then possible to go ahead with the ambulation and further rehabilitation of the patient. It is important to use extreme conservatism in picking the cases for this operation. The question of the treatment of pain in the spinal cases has been a problem. I have seen a fairly large group of patients with cauda equina lesions and severe pain in the lower extremities. The majority of these cases are much relieved by exploration of the cauda equina, which I believe has the same results as neurolysis in certain painful peripheral nerve lesions. I have tried sympathectomy for relief of this type of pain in 2 instances without benefit. The method of choice in relieving the pain in this group of patients is a high dorsal chordotomy.

LIEUTENANT COLONEL FRANK MAYFIELD, M. C., A. U. S.: I should like to say a word of caution with regard to rhizotomy and other destructive operations designed for the control of

massed reflexes. Cases that require this operation are rare, and it should be deferred for at least a year after injury unless there is absolute proof that the cord has been completely transected. Many of these tend to become less forceful and less easily excitable with the passage of time. It seems that the attending doctor is more anxious to do something about these massed reflexes than the patient or the nurses and attendants who care for them. Unless these reflexes are definitely interfering with nutrition or the care of the skin and bladder, I don't believe such an operation should be done.

LIEUTENANT COLONEL CONDUCT W. CUTLER, M. C., A. U. S.: During the past year 67 patients of this type have been admitted to Cushing General Hospital. Ninety-two per cent of cord injuries were caused by gunshot wounds and shell fire. Eight per cent were crushing injuries. Of 64 patients 3 had cervical spine injuries, 44 dorsal spine injuries and 17 lumbar spine injuries. Twenty-five per cent had incomplete paralysis with sufficient motor function of the legs to permit walking with braces. Two who had complete paraplegia on admission developed nearly normal recovery in three months' time. All patients on admission had paraplegia or paraparesis of a flaccid type. From three to nine months was required for a return of deep reflexes and Babinski. The sensory level was sharply demarcated. Twelve patients presented complete sympathectomy effect. Twenty showed increased sympathetic tone with cold moist feet. All but 1 had flaccid paralysis of the bladder. Three patients with priapism had contusion rather than transection of the cervical or dorsal cord. To date no case which on admission showed no flicker of motion in the foot or leg has shown any improvement up to one year's hospitalization. Only 2 cases of cauda equina lesion which showed no flicker of motion on admission showed later improvement. In 67 cases of paraplegia, 34 laminectomies have been done overseas. Fourteen laminectomies were done in this hospital because of total manometric block or in order to determine prognosis and the justification for anterior root resection of the lumbosacral roots to diminish spasm. All laminectomies at Cushing were discontinued in December 1944, as directed by the Surgeon General. In 48 cases of laminectomy, both those done overseas and here, the following findings were recorded: 10 cases, transection; 14 cases, normal cord; 11 cases, contused cord. In 48 cases of laminectomy 16 eventually improved, and sufficient function developed to permit walking. Twenty-two have shown no improvement in one to twelve months. It is to be inferred that these 22 cases of nonimprovement include the 10 cases of transection and some of the cases of contused cord. Fourteen laminectomies done at Cushing Hospital were late operations, generally several months after injury. The findings were about equally divided between normal appearing cord, transection of the cord and contused cord. Four have shown improvement.

LIEUTENANT COLONEL BARNES WOODHALL, M. C., A. U. S.: Neurologic opinions concerning these problems are fairly well established. There is no question that we have a definite responsibility to relieve pain, although it must be admitted that this symptom may vary considerably from patient to patient. The pain associated with the presence of large foreign bodies is a clearcut syndrome and is easily relieved. In cauda equina lesions neurolysis will often diminish the pain sometimes encountered in such patients. I have been impressed by the operative relief of this type of pain noted in overseas reports. I agree with Lieutenant Colonel McCravy that chordotomy is an operation that we have used too infrequently. We have very little to lose with this procedure and the results have been good in the hands of competent surgeons. I am in complete accord with Major Elkins concerning the problem of reducing mass spinal reflexes. The problem, however, is not always as simple as that demonstrated by his patient. In these severe instances where the spinal injury is complete anterior rhizotomy must be done. In the incomplete cases conservative measures of restraint should be followed together with the entire regimen of paraplegic care. Such spinal reflexes then have a tendency toward spontaneous resolution. Exploratory laminectomy in uncomplicated spinal cord lesions is of dubious value. One should not expect neurologic improvement at a late date. Among 35 cases of paraplegia in which operation

was performed within a time period of three hours to five days after injury, 57 per cent showed improvement. Among 386 cases in which operation was performed at a later date in base general hospitals, 10 per cent showed improvement. Colonel McCravey has reported but 1 case showing evidence of improvement out of 6 late after injury. In other groups of cases of paraplegia in which operation was performed three to four months after injury there was failure to show neurologic improvement which could be correlated with the operative procedure. Any objection to exploratory laminectomy naturally does not apply to cauda equina lesions, in which the presence of foreign bodies, depressed bone fragments, inadequate early operation or pain appears to be an indication for exploration.

LIEUTENANT COLONEL SPENCER BRADEN, M. C., A. U. S.: I agree with Colonel Woodhall that discretion should be exercised in the selection of cases for operation for the relief of mass reflexes. We have, at Nichols General Hospital, been trying very hard to dodge the issue of operation in this type of case. We have recently, at the suggestion of one of our internists, Capt. David F. James, been using curare in an effort to control the painful spasms in these cases. We were fortunate in obtaining the cooperation of the Surgeon General's Office in this matter. We have used the drug in varying doses of from 10 to 100 mg. in 5 cases. It is too early to formulate a definite opinion, but we do feel that it may possess very definite possibilities. This drug has been used by anesthesiologists in conjunction with general anesthetic agents for the purpose of promoting greater muscular relaxation. One patient has been relieved of his painful spasms for as long as ten to fifteen hours. Prior to its administration he had experienced great difficulty in obtaining a night's rest, and physical therapeutic procedures were exceedingly difficult because of the reflexes. We have observed no contraindicating deleterious effects even after administration of 100 mg. of the drug. Slight transitory diplopia has been complained of, with an associated feeling of slight unreality. In the evaluation of results of operative intervention in cases of paraplegia a sharp line of distinction should be drawn between the cauda equina and the spinal cord. The cauda equina has the characteristics of and is in essence a peripheral nerve and one would therefore expect it to behave in a similar manner. It can withstand trauma and be expected to recover, whereas the same situation in the spinal cord proper would be hopeless.

MAJOR CHARLES W. ELKINS: I am glad that the feeling toward conservatism has been made evident. The 3 cases of rhizotomy performed at this hospital were on proved complete lesions. One might consider the possibility that posterior instead of anterior rhizotomy be performed to control spinal reflexes. Dr. Frazier did this in 1911 on a patient with spastic paraplegia, syphilitic in origin. The patient did not live long enough to permit evaluation of results, and no autopsy was performed. To my knowledge nothing further has been reported on this procedure and I think it should probably be considered.

The Paralyzed Patient: Urologic Aspects

CAPTAIN BORIS P. PETROFF, M. C., A. U. S.: At Newton D. Baker General Hospital 70 patients with spinal cord injuries have been received since September 1944. These include complete and partial traumatic myelitis at levels from the seventh cervical down to cauda equina injuries. Forty of these had suprapubic cystostomies performed overseas. This report deals with these 40 patients with suprapubic cystostomy and the reestablishment of urethral voiding in 17 of them. Urea nitrogen and carbon dioxide combining power are obtained and intravenous urograms, which are extremely valuable as a matter of record so that a comparison may be made with later plates in case a febrile reaction develops as the result of urinary complications. The suprapubic tube is checked for its adequacy, changed if necessary and connected to the closed system, manually controlled type of drainage and irrigation, so that the patient can irrigate himself with the M citric acid buffered solution (Suby and Albright: *New England J. Med.* 225:81 [Jan. 21] 1943). As soon as the patient's condition warrants it, the suprapubic tube is removed, the sinus

packed and a urethral catheter is inserted. We use a small caliber catheter such as a No. 16 or No. 18 French, with added holes cut in its tip for better drainage in an attempt to avoid the occurrence of periurethral abscesses and epididymitis. Of the 38 patients changed from suprapubic drainage to catheter drainage in the past nine months, 6 have developed periurethral abscesses at the penoscrotal junction followed by fistula formation, and 4 have developed epididymitis, 1 of which was bilateral. Another patient who had both abscess and epididymitis came to orchiectomy. These periurethral abscesses occurred during use of the 22 F. Foley self-retaining catheter in an attempt to avoid using adhesive tape on the penis, especially because priapism tends to pull the straight catheter out. These abscesses might have been avoided if smaller catheters had been employed or if a No. 18 self-retaining 5 cc. bag catheter had been available instead of the larger sizes. Catheters of large size may cause necrosis of the urethral mucosa at the penoscrotal angle and lead to abscess formation. A urethral fistula which heals slowly, rived in slowness only by the perineal urethrostomy, represents a decided handicap to the spontaneous activity of which some of these six bladders are now capable. An attempt is being made now to speed the closing of these fistulas by suture with stainless steel wire, and it is difficult to state at this time what the eventual status of patients with this complication will be.

As for epididymitis, we recently had a case which developed even though no catheter over No. 16 was ever used. The question has come up regarding ligation of the vas deferens in conjunction with a urethral catheter to prevent epididymitis, but the youthful age group and the possible effect on the patients' morale have been against it. They all hope for an active sex life.

The change from suprapubic tube to urethral catheter is always a big lift to a patient's morale, as the cystostomy is repugnant to most of them. The sinus heals in from two to six weeks. A cystourethrogram is done as a matter of record. Cystometric readings are taken as soon as the cystostomy heals and sometimes through the cystostomy tube if there is not undue leakage around it. Cystometric curves have been very valuable in differentiating between the hypotonic bladder and the hypertonic small bladder aggravated by mass reflexes. These mass reflexes are a great problem, as urine escapes around the catheter and keeps the patient wet whenever the bladder contracts spasmodically. The cystometric curve also indicates when the patient has established a reflex bladder and the catheter can be dispensed with. The main procedure in rehabilitating the bladder in establishing a reflex bladder of good capacity is institution of tidal drainage apparatus. The Stewart-Munro modification is the one used here and has given very good results.

Of the 38 patients who have been placed on urethral drainage in this hospital, 30 have had tidal drainage apparatus irrigating and exercising their bladder for one to three months. Seventeen are voiding now with little, if any, urinary residual and all have shown increased bladder capacity, which has advanced most of them from 50 to 75 cc. to 300 to 400 cc. bladder volume as contrasted to 1 who did not get tidal drainage and remained with a small capacity bladder and a suprapubic cystostomy. Of the remaining 8 patients on urethral drainage without tidal irrigation, 4 had cauda equina injuries and 4 are those whose cystostomies have not yet healed. In time, with tidal drainage, we expect those patients with complete cord lesions to void by reflex action. So far, those with high thoracic or cervical transverse complete myelitis seem to be the slowest to respond to automatic irrigation. Those with partial myelitis have resumed bladder activity in three to four months. While on tidal irrigation, the constant inflow and outflow of M solution keeps the bladders clean and the walls elastic. M solution has been the best for irrigating purposes. It is composed of citric acid buffered with magnesium oxide and sodium carbonate and has a pH of 4.5. Although it will not completely prevent calculus formation in the bladder or destroy bacteria, it has given better results than 0.5 per cent acetic acid or boric acid, which we used at first.

The most pressing problem in keeping these paralyzed patients alive and reasonably well is to combat urinary infections attended by chills, fever and calculus formations. All our urinary flora now contain *Aerobacter aerogenes*, *Proteus vulgaris* and *Bacillus pyocyaneus* and occasionally *Escherichia coli*. The staphylococcus and streptococcus have been cleared up by penicillin therapy. After each chill and elevated temperature, a blood culture is taken. We have had three positive blood cultures, two for *Aerobacter aerogenes* and one for *Proteus vulgaris*, later followed by *Bacillus pyocyaneus*. All three became negative in three to four days following increased doses of penicillin, blood transfusions, relief of ureteral obstruction and forcing fluids, as well as supportive measures such as the oxygen tent, and digitalis therapy administered by the medical service. The gram-negative organisms which infect the urinary tract cannot be eliminated by penicillin as can the staphylococcus and streptococcus groups. They also have urea-splitting properties, causing the formation of alkaline calculi in the bladder and kidneys. Of 40 catheter or cystostomy patients who have had intravenous pyelograms and observation cystoscopies of the bladder, 28 had bladder stones of varying size and hardness, composed of calcium and magnesium carbonate and phosphates. All these urines contained *Aerobacter aerogenes* and *Proteus vulgaris*. These calculi are ever present. Patients with suprapubic drainage had them and after they had been removed and urethral drainage had been instituted within a few months they had recurred in the bladder. These bladder stones are easily removed by the Elikk evacuator through the panendoscope sheath, but the larger ones have to be crushed first with a visual lithotrite. Demineralization of the bones in recumbent patients as demonstrable by osteoporosis in x-rays, resulting in increased calcium salts in the urine and stasis in the bladder due to incomplete emptying by catheter, especially the Foley bag catheter, which may allow puddling of urine behind the retaining balloon, may account for these bladder calculi, but the gram-negative urea splitting bacilli are the probable factors at the bottom of this stone formation.

The treatment of upper urinary tract infection has been difficult. Of 43 paralyzed, bedfast patients, 8 have developed renal calculi. The paralyzed patient with a high spinal cord lesion cannot localize renal pain, and the diagnosis of renal calculi depends on intravenous urograms, which are taken as soon as the patient develops abdominal distress, vomiting, distention, chills or fever. Of these 8 patients with kidney stones, 2 have had to have operations for urethral obstruction. One had to have a nephrectomy because of cortical abscesses and stone, and the second had a pyelolithotomy and since has had another stone obstructing the ureter. Three others responded to more conservative measures of passing a catheter up to the obstructed kidney as, fortunately, the calculi were small. One death was due to a pyonephrosis and lung abscess as well as to ureteral calculi, the culture of the renal abscesses showing *Aerobacter aerogenes*. Penicillin, sulfonamides and blood transfusions combined with general medical and surgical care have served to keep these patients alive so far by combating streptococcal and staphylococcal infection.

Aseptic care of the catheter tidal drainage apparatus and collecting bottle and tubing are taught to each corpsman in the ward. Two specialists are on duty all the time for urologic care only. The patient himself is instructed as to how to avoid contaminating his catheter in an attempt to reduce the incidence of infection. The paralyzed patient will be most benefited by general building up of his resistance to infection, and the urologist will do the most good by conservative treatment and careful watching and waiting, using every diagnostic and therapeutic method at his disposal to forestall ureteral obstruction and blood stream infections, hoping to avoid complications until a time when the patient can dispense with catheters and be on his own with a reflex bladder or voluntary voiding.

In summary, of 70 patients with spinal cord injuries, 40 who had suprapubic cystostomies have been, or are being, placed on urethral drainage, which has enabled 17 of them, so far, to empty their bladders by voiding with little if any residual. Urethral catheters caused complications, such as

periurethral abscesses in 6 cases and epididymitis in 4 cases of the total of 38 with urethral indwelling catheters. Urinary infections have been predominantly due to gram-negative organisms, and formation of bladder calculi was high. Renal calculi were found in 8 of the total 70, mostly among the 43 seriously injured patients whose physical activity has been limited.

Patients with spinal cord injury who have had suprapubic cystostomy for transportation purposes overseas should be given a chance to reestablish some form of voiding through the urethra. This is done by inserting a urethral catheter of small caliber and instituting tidal drainage. The complications of the urethral catheter, such as periurethral abscesses with fistula formation and epididymitis, can be partly reduced by avoiding the use of any catheter over No. 18 French in size. The patient's condition must be good before the change from suprapubic to urethral drainage is made. The end result of a good percentage of voiding patients would seem to justify this course of action. Urinary infections can be controlled by sulfonamides, penicillin and the new antibiotics which help to destroy gram-negative organisms. Urologic complications of the upper urinary tract must be expected and constant watch kept for renal calculi and abscess formation. These are treated in the most conservative fashion. The urologic management of the paralyzed patient is a constant struggle against many odds, but the end result of a voiding, upright, infection free individual is worth the fight.

Associated Complications in War Wounds of the Spine

CAPTAIN WILLIAM C. WARD and MAJOR G. L. MALTBY, M. C., A. U. S.: At present there are 32 cases being cared for jointly by the neurosurgical and genitourinary sections at the Ashford General Hospital, White Sulphur Springs, W. Va. The entire group had, in addition to the usual decubitus ulcers and urinary tract pathologic conditions, associated injuries to the peripheral nerves and peripheral blood vessels, compound fractures, traumatic amputations, penetrating wounds of the chest and penetrating wounds of the abdomen requiring colostomy. Spastic disorders in the complete and near complete cord lesions have likewise been quite a problem.

The following cases represent the less common problems that have appeared in this group:

CASE 1.—*Fecal fistula through the spine.* On July 6, 1944 a private sustained a shell fragment wound of the spine in the region of the fifth lumbar vertebra. On July 7 a laparotomy was done. The amount of injury to the intestine is not described; however, he had generalized peritonitis at the time. A cystostomy was done for rupture of the bladder. The wound in the region of the lumbar spine was debrided. Later he was found to have drainage of fecal material through the wound in the lumbar region. He also had drainage of feces and urine from the suprapubic tube. On July 29 an exploratory laparotomy was done, and a loop of small intestine was found to communicate with the bladder. The source of drainage of feces through the wound in the back was not found. Postoperatively the patient did very well. However, the upper end of the abdominal incision opened and drained fecal material but no urine. Physical examination revealed a midline abdominal incision with drainage of fecal material and pus from the lower portion. There was an extensively scarred wound measuring 3 by 4 cm. in the midline of the back at the level of the second lumbar vertebra. Immediately beneath this scarred area was an area of fluctuation, and pressure on this caused purulent material to be expressed from the wound. There was pronounced atrophy of all the muscles of both lower extremities. However, the patient was able to move the toes of both feet a little. There was an area of anesthesia over both buttocks and the posterior aspect of both thighs. On numerous occasions he had noted the passage of gas through the draining wound in the lumbar region. On December 4 a barium enema was given and the film showed a fistulous tract extending from the distal portion of the sigmoid superiorly into the region of the fourth lumbar vertebra. On Feb. 5, 1944 the draining sinus was injected with iodized oil. This revealed that the sinus extended into the

fifth lumbar interspace and proceeded through the sacrum to enter the intestinal tract. Films made one hour later revealed oil in the sigmoid. On March 15 two small pieces of bone extruded from the wound in the back. He continued to have a considerable amount of purulent drainage from this wound in addition to gas. On April 7 a transverse colostomy was done. There has been less drainage from the wound in the back since that time; however, the patient does continue to pass a small amount of gas occasionally through this wound. Further exploration is now considered.

CASE 2.—Urinary fistula through spine. On June 1, 1944 a private sustained a shell fragment wound of the spine in the region of the fifth lumbar vertebra with immediate paralysis of both legs and a rigid abdomen. Exploration revealed a large retroperitoneal hemorrhage. A pyelogram revealed an injury to the left ureter. On July 25 an exploration was made of the left ureter and a foreign body was removed. A catheter was inserted into the ureter. Examination revealed several draining wounds over the back in the region of the fifth lumbar spine. There was a complete paralysis of the entire right lower extremity; however, the patient showed some function of the left quadriceps muscle. There has been urinary drainage from the wound in the back. An intravenous pyelogram did not reveal any definite injury to the left ureter. Following this the patient's general condition gradually improved. Most of the wounds on the back healed. One small area continued to drain purulent material and intermittently drained urine. On Feb. 10, 1945 the sinus was injected with iodized oil. The sinus tract passed down through the left sacroiliac joint and proceeded to enter the left ureter near its distal end; the oil then ascended the ureter to the level of the fourth lumbar vertebra. Films made twenty-four hours later showed a small amount of oil in the left kidney and in the bladder. The intravenous pyelogram was repeated on February 14 and revealed a small stone in the ureter apparently at the site of the fistula. Urine continued to drain from the sinus and could be demonstrated by methylene blue given by mouth. On March 14 the left kidney was removed. There was no further drainage of urine from the wound in the back. However, there persisted some drainage of pus. On May 2 the sinus tract was explored and several small fragments of bone were removed.

CASE 3.—Chronic recurrent meningitis. On Nov. 19, 1944 a private sustained a shell fragment wound of the spine in the region of the third lumbar vertebra. He had immediate complete paralysis of the lower extremities. A laminectomy was done and a small shell fragment was found lying alongside the cord, with laceration of the third lumbar root. Postoperatively the patient was able to move the feet and legs a small amount. He developed a spinal fluid fistula at the site of the original wound. On December 16 the spinal fluid drainage stopped and the patient became quite ill with high temperature (104 F.), stiff neck and rapid pulse. He stated that he had been having a low grade fever and had had frequent severe left frontal headaches since the middle of December. Examination revealed a small, well healed wound just to the left of the spine in the region of the third lumbar vertebra. There was a well healed laminectomy wound which extended from the first lumbar to the third lumbar. There were weak contractions of both quadriceps muscles. No other motor function was noted. There was hypesthesia over both lower extremities below the level of the second lumbar dermatome. There was an extreme degree of emaciation. On Jan. 29, 1945 an intravenous pyelogram revealed slight hydronephrosis of the right kidney; the left kidney was completely blocked. It was thought that the persistent fever and extreme emaciation were due to this. On January 31 the left kidney was removed and found to contain thick pus and abscesses. Postoperatively the patient felt much better and appeared improved. Ten days later he developed sudden onset of severe left frontal headache. This was associated with a rise in temperature to 103 F. A spinal puncture was done which revealed a white cell count of 4,408, with 99 per cent polymorphonuclears. Culture of the spinal fluid was negative. During the next two days the temperature subsided. Two days later a spinal puncture revealed a white cell count of

800, and culture revealed *Bacillus pyocyaneus*. The patient's condition gradually improved. On March 15 the patient developed a temperature of 104 F., became irrational, with a pulse of 160, and appeared critically ill. Spinal puncture revealed 2,000 white cells. The next morning the patient's temperature was 99 F., he was rational, and he appeared greatly improved. On March 26 he had a similar episode, with a temperature of 102 F. On April 15 he again had a similar episode of headache, slight fever and stiffness of the neck. X-ray of the lumbar spine revealed no sequestrum. Under local anesthesia on April 26 a small area of the laminectomy wound was opened. The epidural fat was edematous, but no pockets of pus were found. A drain was placed in the extradural space. Since that time the patient has shown slight improvement but has had one mild attack of headache associated with fever.

These cases represent uncommon complications as found in 88 cases of spinal cord and cauda equina injuries. Injection of draining sinuses with iodized oil has helped in determining the extent of the cavities, their locations and frequently the indicated treatment.

DISCUSSION

CAPTAIN HAROLD LIPSHUTZ, M. C., A. U. S.: In treatment of paraplegic patients at Wakeman General Hospital we have found that cystoscopy is a necessary procedure. This has been impressed on us because of the great number of cases arriving at our hospital from overseas with bladder calculi. Recently, 5 out of 7 cases presented multiple bladder calculi at the time of admission to the hospital. Cystoscopy should be done as soon after arrival of the patient as is possible, preferably within forty-eight hours. There is a point that should be stressed concerning the time of removal of all catheters. Cystometric readings, although valuable, cannot be depended on, because the most important factor is the presence or absence of spasm of vesical sphincters. When the sphincters are fully relaxed, the Cunningham incontinence clamp suffices for urinary control. In the presence of good detrusor function, accompanied with refractory spasm of the vesical sphincters, it is possible that electrical destruction of the sphincteric control will be the answer. I should like to ask one question of the neurosurgeons: We have always been taught that automatic bladder function or voluntary bladder control cannot be attained in the presence of destruction of the third sacral nerve supply to the urinary bladder (nervi erigentes), yet our best results with return of voluntary bladder control have been in cases of recovering partial paraplegia in which these nerves have been damaged.

LIEUTENANT COLONEL CONDUCT W. CUTLER, M. C., A. U. S.: Indwelling urethral catheters in these cases are undesirable because of complicating infections and epididymitis. Bladder function has not returned more rapidly when urethral catheters have been employed than with suprapubic drainage. Drainage through the perineal urethrotomy wound has proved satisfactory in that it provides good drainage and is not associated with complications. Such wounds have closed rapidly after removal of the catheter. The number of cases in this group has been too small to justify the drawing of conclusions. Tidal drainage has succeeded, where appropriate, in keeping the bladder clean and free of infection. It has been the general observation that the development of automatic bladders is rather slower in these paraplegic cases than in civil practice. It has been proposed that better and more rapid results might attend the use of a perineal urethrotomy with indwelling catheter, permitting the secondary surgical closure of suprapubic cystostomy wounds once infection has been controlled. It is believed that the automatic bladder would develop more rapidly under these conditions.

CAPTAIN GEORGE O. BAUMRUCKER, M. C., A. U. S.: I should like to discuss some of our results in these cases from my services at the Gardiner General Hospital and the Hines Veteran Hospital in Chicago. An unusual complication was presented in 1 of these cases resulting in death. The bullet that transected the spinal cord cut the right ureteropelvic junction and lodged in the diaphragm. Skiodan injected into the bladder refluxed back up into both kidneys, explaining the pyelonephritis. Dye injected into the right flank fistula showed extravasation into the right flank and made a pyelogram of

the right kidney. Both trochanters were protruding through large hip ulcers. Excision of these made nursing care easier, but the patient's course was rapidly downward and he died in spite of penicillin, plasma, blood transfusions and sulfonamide drugs. This new information that we have now regarding the large amounts of serum protein loss from these bed sores may be the factor in prolonging the lives in similar cases and preventing this severe emaciation, which too often occurs in these cases with large bed sores. We do not use tidal drainage. We use a closed system of bladder lavage set up with a special two way clamp. It is fool proof, is simple and needs no specialized care. It can be easily taken care of both by patients and by nurses. Pressure of the fingers allows the bladder to be filled, and release of the pressure allows fluid to run out of the bladder. By this technic we are able to correct the spastic and small capacity bladder, so that, when automaticity does set in, the bladder will have a bigger capacity and be more elastic. We use a cystometer which registers full bladder pressure and volume simultaneously. It has been our experience that those bladders with 100 to 150 cc. volume that can exert a pressure of over 40 mm. of mercury pressure either reflexly or by intra-abdominal pressure will successfully empty to a low residual and need no further catheter drainage. Urethral catheters get along about as well as suprapubic catheters and sometimes better if the suprapubic catheters leak, provided the urethral catheters are changed frequently and kept clean and irrigated. Otherwise, of course, if neglected periurethral abscesses are common. For the most part the cystostomy tubes inserted overseas are properly placed and located and fit well. However, those very few that were found unsatisfactory were so because of three reasons: 1. Too low an insertion in the abdominal wall, causing pressure of tube against symphysis pubis with, of course, the potential danger of bone involvement. 2. Too low an insertion in the bladder itself, causing pressure of the end of the catheter against the trigone, which often produces spasm and discomfort. 3. Lack of support of the bladder to the rectus muscle, causing a false pocket of urine between the bladder and the abdominal wall, making replacement of the suprapubic catheter very difficult.

CAPTAIN JAMES SEMANS, M. C., A. U. S.: At McGuire General Hospital we have over 30 paraplegic patients with catheters in place. Twenty of these have suprapubic drainage. Suprapubic cystoscopy has proved to be a valuable procedure. By passing the cystoscope through the suprapubic tract, it is possible not only to examine the interior of the bladder but also to remove encrusted mucosa and stones. My impression is that the patient has less cystoscopic reaction than by the transurethral route. The drainage of the bladder with the suprapubic catheter has been improved a great deal by rolling the patient on to his abdomen while irrigating the catheter. The gravitation of the exudate toward the suprapubic catheter facilitates its removal. In the supine position only the supernatant exudate is removed. I can see a problem, namely whether or not it is preferable to allow the sinus tract to close early and to treat the bladder transurethraly or to treat the bladder suprapubically until it is permanently free of exudate and stones, and then to allow the sinus tract to close, reasonably expecting to have no more difficulty afterward.

Urinary Calculi in Recumbent Patients

MAJOR JAMES J. JOELSON, M. C., A. U. S.: In a period of seven months we have encountered 31 cases of urinary calculi in recumbent patients at the Crile General Hospital. In 26 the primary cause of recumbency was a compound fracture, usually with osteomyelitis, of one or more long bones of the lower extremity or of the bones of the pelvis. Four patients had severe injuries to the abdominal viscera. Eighty-nine per cent were casualties from the European theater of operations, indicating that a tropical climate is not necessarily a factor in the formation of renal stones of recumbency. The shortest period of recumbency was one month and the longest was nine months, the average being four months. The shortest period between the initial injury and the onset of urinary symptoms was three months and the longest was nine months, with an average of four and one-half months. Twelve of the 31

patients had a single calculus, and 19 had multiple stones. In 23 of the patients the stones were unilateral and in 8 they were bilateral. They varied in size from 2 or 3 mm. to 2 cm. in diameter. All of the 31 patients had hematuria, either gross or microscopic, but only 13 showed any pus in the urine, and of these only 5 had a serious infection. The pH of the urine before treatment was started varied between 5.5 and 7.5, with an average of 6.5. The stones were demonstrable by x-ray in 24 cases (about 77 per cent). In the other 7 cases the diagnosis was proved by the passage of one or more stones. The analysis of the recovered stones showed them all to be calcium stones; 70 per cent were calcium phosphate and 30 per cent were calcium oxalate. Seventy-five per cent of the phosphatic stones showed also the presence of some oxalate, and 50 per cent of the oxalate stones showed traces of phosphate. Only one stone in this series showed a positive test for sulfonamides. The serum calcium, blood phosphorus and phosphatase (alkaline) were normal in all of the cases. The Sulkowitch test for the amount of calcium in the urine was done in 12 cases and found to be definitely elevated in 4 (33 per cent), indicating that a hypercalciuria may persist in some of these patients for more than two months. The great majority of our patients were treated conservatively. They were placed on a high fluid intake of at least 4,000 cc. a day. The acidity of the urine was increased by means of a high acid ash diet, and, if the daily pH determinations indicated it, the diet was augmented with ammonium chloride. Also these patients were got out of bed as soon as this could be safely accomplished, and if this was not possible an effort was made to change their position in bed frequently. Cystoscopy was avoided if possible in the uninfected cases, although cystoscopic manipulations were utilized when infection had already occurred or when there were definite indications for this form of treatment. By this general scheme of therapy satisfactory results were obtained in a high percentage. In 1 case a most dramatic result of dissolution of the bilateral stones was obtained; in 16 cases the stone or stones were all passed; 4 patients have either passed some of their stones or have shown a decrease in the size of the stones; 2 have shown no improvement and will probably require operation; 5 will undoubtedly require surgical intervention, and 3 have already been operated on. Solution G (Suby and Albright) has been used for 4 patients, through either a nephrostomy tube or a two-way ureteral catheter, without any appreciable results. In this series of cases there were two deaths from renal insufficiency and severe pyelonephritis.

The enforced recumbency acts in two ways: first by causing a hypercalciuria and second by allowing the sediment that forms in the calices to remain there and increase in size. Another factor which seems to favor the formation and growth of these calculi is the infection which is present with the complicating osteomyelitis. The possibility of sulfonamide crystals as the primary nidus for the formation of these stones must be seriously considered. They were found in only one stone; the other stone in the same renal pelvis did not contain any sulfonamide. The acidity of the urine is another extremely important factor in the formation of these stones. Calcium phosphate, which is present in most of the stones of recumbency, will precipitate in an alkaline urine but will usually remain in solution in an acid urine.

During the first phase of the condition, the treatment may be outlined as follows: 1. Fluid intake. 2. Diet: (a) a high acid ash or neutral ash, (b) elimination of milk, (c) elimination of fruit juices, (d) vitamins. 3. Medication: (a) urinary acidifiers, (b) urinary antiseptics. 4. Movement of the patient. 5. Laboratory studies necessary for the proper diagnosis and treatment. Milk should be eliminated, for this food definitely increases the amount of calcium excreted in the urine, and it has been demonstrated that a high calcium diet will double the urinary output of calcium. Another dietary error consists in giving these patients large amounts of fruit juice, since it is believed by some that the contained vitamins are beneficial to proper bone repair. If this is true, the necessary vitamins could easily be given in pill or capsule form and thus the alkalization of the urine by the fruit juices could be avoided. The ingestion of large amounts of both fruit juice and milk results in a highly alkaline urine containing large amounts of calcium, the most perfect combination

possible for the formation of renal lithiasis and for the continued and rapid growth of the stones. The diet should have a high vitamin A content.

It is advisable that frequent microscopic examinations of the urine be done so that the infection can be recognized early and proper steps taken. The sulfonamides are probably the most useful drugs in the treatment of these infections. Sulfacetamide shows the greatest solubility in either an acid or an alkaline urine and therefore does not form sulfonamide crystals in the renal pelvis or calices around which further stones may form. Movement of the patient, either active or passive, is essential. Patients who are completely immobilized should be turned at least once a day, if possible, in an effort to allow the dependent minor calices to empty themselves of any sedimentary particles which may have collected there. As soon as it can be safely accomplished, these patients should be got out of bed and encouraged to take as much active motion as their disability will allow. The Sulkowitch test is a relatively simple procedure which gives a fairly accurate indication of the amount of calcium contained in the urine and may be an aid in determining whether the acid regimen is causing an increase in the hypercalcinuria. In 258 consecutive cases of fractures of the lower extremity, routine films of the urinary tract were done. In not one of these was there a calculus demonstrated which had not been suspected because of clinical symptoms or microscopic hematuria. It seems, therefore, that repeated microscopic examinations of the urine will be more helpful than an occasional routine x-ray film in detecting these calculi of recumbency.

The treatment of the second phase of renal calculi of recumbency presents the urologist with many difficult and serious problems. These patients should immediately be placed on the therapeutic regimen outlined for the first phase and thoroughly studied. Unless there are definite contraindications, they are kept on this treatment for months. During this time the acid urine may completely or partially dissolve some of the stones and many of the stones will be passed spontaneously. Seventeen of our 31 patients have already passed or dissolved all their stones. Cystoscopy should be avoided if possible in all uninfected cases because the danger of introducing infection into the fertile soil of these urinary tracts is a definite possibility and the superimposed infection makes the condition infinitely more serious. Surgery should be delayed if possible until conservative treatment has been given an adequate trial and until the patient's general condition is such that surgery can be safely undertaken. Also it is desirable to have had the patient out of bed for some time before operating and thus overcome the hypercalcinuria, with its tendency toward reformation of stones. X-ray evidence that the stones have stopped increasing in size or number is reassuring information to have before operation, since it indicates that the chance of recurrence is much less. Occasionally, however, the surgeon's hand will be forced by various conditions or complications which will necessitate surgery before these optimum conditions are obtained. The type of operation to be done will be determined by the conditions present and by the experience and judgment of the surgeon.

Nonsurgical Treatment of Urinary Stone

MAJOR FRANK C. HAMM, M. C., A. U. S.: The various methods of nonsurgical treatment of urinary stone are of value principally in the prevention of stone formation. Once a calculus has formed and has obtained sufficient size to be of clinical importance, its removal is accomplished best by surgery. The disposal of urinary stones, either by dietary measures or by any of the dissolving solutions, should be reserved for only those cases in which surgery is contraindicated. Our experience to date, while limited, has not been encouraging with stone dissolving agent solution G, owing principally to the irritation of the solution and to the discomfort of the treatment imposed by the long period required, especially with the indwelling ureteral catheter method.

For prevention of stone, the following procedures may be safely recommended:

1. Increased fluid output, a minimum of 2,500 cc. each twenty-four hours. This would probably require an average intake of about 4 liters.

2. A high calory, high vitamin diet. The p_H of the urine should be checked so that the diet can be regulated to prevent the urine from becoming neutral or alkaline. The routine use of an acid ash diet is not recommended at the present time.

3. Eradication of foci of urinary infection.

4. Stasis. Surgical treatment is required for anatomic obstructions. Stasis of immobilization and recumbency must be corrected by getting these patients moving earlier. An erect position, either sitting or standing, should be stressed. Patients immobilized by casts and apparatus should be turned on a Stryker frame. Turning a patient every two hours is not enough.

5. Urinalysis once a week to detect urinary infections.

6. Hyperparathyroidism. In recurrent stone cases urinary calcium determinations should be made following a three day calcium free diet.

7. Dissolution. In instances in which stones have already formed, attempts at dissolution should be made only when surgery is contraindicated. It should be given discontinuously, and preferably through a nephrostomy tube. The use of enzymes (urease) is not recommended.

The application of these principles has greatly reduced the recurrences of stone and in an occasional instance has been credited with the dissolution or disappearance of the stone.

DISCUSSION

MAJOR ROTH, M. C., A. U. S.: I should like to show x-ray films taken of unusual types of stones in recumbency. I have never seen this type of case in civilian practice. The first patient was a man aged 23 with a fracture of the femur. He had been in bed for six months. He had no urinary symptoms, but, in routine check of the urine, red blood cells and white blood cells were found. A flat x-ray plate and intravenous pyelogram showed a column of sedimentary stones impacted in the lower third of the right ureter, causing obstruction and diminution of function of the right kidney. Fortunately, the patient passed these crystals of sedimentary calculi spontaneously. Following this the kidney function returned promptly. The second patient was a young man who had fractures of the femur and of the shoulder and who had been recumbent for six months. He was asymptomatic until he was allowed out of bed, whereupon he developed severe left renal colic. In spite of sedation, the colic continued. The flat film of the kidney, ureter and bladder showed an impact of sedimentary stones in the lower third of the left ureter, the column extending from the bladder upward for about 4½ inches. Because of the continued colic, which no sedation would alleviate, cystoscopy was done, but the catheter could not be passed above the column. We continued to treat him conservatively without results. He continued to have colic and a rise in temperature up to 103 F. accompanied by chills. A second cystoscopy was done and a number 5 ureteral catheter was passed up to the left kidney pelvis with great difficulty and left in situ. The urinary drip was definitely hydronephrotic. He continued to have severe colic without any drop in temperature and it was felt that the column of stones would have to be removed. We felt that, if we could remove the bottom of the column, the rest of the sediment would pass spontaneously. This was done cystoscopically and was successful. We obtained 320 mm. of gravel. In addition, the patient had bilateral renal calculi and was therefore placed on a high acid ash diet with great quantities of liquid. Subsequent x-ray examination showed the kidneys free from calculi.

MAJOR ABEL J. LEADER, M. G., A. U. S.: Prophylaxis is probably the most important consideration in these cases. A program of prophylactic management in recumbent patients should be both clearly defined and generally adopted. In a survey of 576 unselected orthopedic patients at Fletcher General Hospital our preliminary figures indicate that of these 212 had abnormal urinary findings. One hundred and fifty cases showed only the presence of a microscopic pyuria, while 62 others showed the presence of various combinations of pus, blood, casts and albumin. Two months immediately following immobilization is the "critical" period. It has been shown that a hypercalcinuria exists for the first sixty days or so after immobilization starts. Because of the time lag between the

first immobilization and the time we see these patients in the general hospitals in the zone of interior we do not have control of the patient during the so-called critical period. It usually takes about two to three months between the time the patient is injured and his hospitalization in the United States. Therefore the prophylactic program during this early period becomes a responsibility of the lower echelons of medical evacuation such as the field and the evacuation hospitals. Here hypercalcinuria, stasis and alkalization of the urine can be effectively combated by a regimen which involves the ingestion of large quantities of water, usually not less than 4 liters a day. Stasis can be effectively combated by turning the patients from the dorsal to the ventral recumbent position for one hour periods at least every two hours. A neutral ash and not a high acid ash diet is advised during the first two months of immobilization, because the use of the latter results in an increase in the hypercalcinuria. By ordinary standards we may think that when a recumbent patient gets 2,500 cc. of fluid per day he is getting enough, but actually because of the hypercalcinuria a relative dehydration exists which requires an intake of at least 1,500 cc. more in order to aid effectively in the elimination of the calcium which otherwise might be precipitated. Fruit juices have an alkaline residue which adversely affects the pH of the urine, and their use should be prohibited. The use of milk should also be discouraged because it too merely increases the amount of calcium which must be excreted by the kidney, which is already pouring out increased amounts. As regards the management of recumbent patients in the general hospital in the zone of the interior, the same principles must be followed through. Now, however, because there is no longer a hypercalcinuria a high acid ash diet is advisable, since-keeping the urine acid and dilute is our objective. Fluid intake must be carefully watched and at least 4,000 cc. taken daily. Frequent change of position and ambulation at the earliest possible time are necessary. The patient in a hip spica must be turned at very frequent intervals and, if in traction, as much free movement of the unimmobilized parts of the body as is possible must be encouraged. A routine kidney, ureter and bladder film is indicated in all cases with a history of recumbency of two months or longer on first coming out of plaster, especially in those in which any abnormal findings have been noted. In those cases in which stone has actually formed to any demonstrable degree, frequent x-ray check-ups at six month periods for at least two years are advisable in order that the serious late effects on the kidney may be avoided.

DR. W. H. TOULSON, Baltimore: The stones that seem to be most troublesome are located in the lower end of the ureter. They will not pass spontaneously; they become larger and cause damage and infection to the ureter and kidney of the affected side. In some instances dense strictures occur in front of these stones that make ureteral dilation by means of a bougie or catheter impossible. It is well known that a normal ureter implanted in another position in the bladder usually offers no problem, but in this infected and dilated type of ureter, where the blood supply is poor, attention must be paid to the details of implanting the ureter. The operation that I present is useful in situations of this character. I have had occasion to use the operation successfully only six times.

MAJOR S. L. RAINES, M. C., A. U. S.: At England General Hospital we care for many patients who are recumbent, since we are an amputation and neurosurgical center. I should like to bring up one matter that has not been mentioned. We are all agreed that just recumbency, with or without amputation or infection, causes calcium to leave the bones and become excreted by and deposited in the kidneys. The underlying cause of this change is not fully understood and will require careful and thorough investigation by workers trained in such procedures. I would suggest that in addition to all the work being done on caring for these patients, after stones are formed, we consider the problem of preventing such movement of the body calcium. It is a biochemical process and I believe a biochemist and such other technical help as is needed could be assigned to study this problem in one of our hospitals where so many men are confined to bed for long periods. Few, if any, civilian groups would have the cases available for such periods of time as our army hospitals have just now.

COLONEL CLAUDE BECK, M. C., A. U. S.: At Fletcher General Hospital I found that Major Leader had been assigned to the fracture ward of the orthopedic service. In a period of six weeks he picked up 13 patients with urinary calculi. This experience suggests the advisability of having a urologist in the orthopedic section so that these complications will be detected. I am interested in the possibility of a nidus for a stone being developed in a patient without showing any evidence of the stone while he is in the hospital. The possibility exists that these patients might develop stones in the urinary tract after they are separated from the Army. This is a problem which may present itself in the future.

MAJOR PETER W. SWEETSER, M. C., A. U. S.: If all this physiology and pathology is true, then the physiology of exercise is true. The use of class IV physical reconditioning will combat stasis and sluggishness. It cannot be proved that kidney stones will be immediately prevented or cured, but exercise in bed is an important adjunct to other treatment. At Newton D. Baker General Hospital we have been giving class IV physical reconditioning routinely to patients in bed. These patients feel better than those who do not have any exercise. They are very receptive and seem to look forward to it. I recommend strongly that the individual medical officer give more attention to the use of physical reconditioning for his patients. The system has been laboriously organized; why not accept its benefits?

DR. JOHN E. HOWARD, Baltimore: Recent observations on the metabolism of calcium in patients at bed rest and in casts and those suffering fractures may be pertinent to this discussion and perhaps change our orientation in our therapeutic efforts. Previously healthy patients with fractured femurs, at bed rest in casts, excrete steadily increasing amounts of calcium in the urine up to a period of approximately thirty days, at which time such calcium excretion reaches a plateau level where it is maintained for a long time, presumably until mobilization of the patient takes place. Smaller increases of urinary calcium occur when healthy patients are simply put to bed in casts without fracture. Studies have been made of the effect of various dietary changes during the plateau period of greatest calcium excretion on such fractured patients and were to me very surprising. A diet which contained minimal quantities of calcium, for example 0.2 Gm. daily, was carried on for a period of a week or two and then changed to one containing 2 Gm. of calcium or higher in the form of milk. Then the original diet was resorted to again for a period of observation. There was little or no change in the amount of urinary calcium excretion following these dietary changes. Even if calcium in the form of lactate was given in large amounts, but little increase in the amount excreted in the urine was found. Doses of vitamin D far in excess of the usual therapeutic levels also seemed to make but little difference in the amount of calcium which appeared in the urine. I was unable to detect any change in the urinary calcium excretion from the administration of sulfonamide compounds. Thus one wonders whether the strict elimination of milk and vitamin D from the diet and the restriction of sunlight to these patients is really serving the desired purpose. Under the circumstances of bed rest and immobilization for fracture, the bones rarely and the movement of lime salts out of such bones is transferred from the blood to the kidneys and is excreted via the urine. The excess quantities of calcium thus appearing in the urine must surely be a major factor in the production of stones in these patients. These stones are almost invariably calcium phosphate or carbonate in character. We have as yet no true idea of the circumstances or stimuli which induce bone cells to make new bone or what stimuli induce bone resorption. It seems very likely that the bone cells themselves are metabolically active in both of these procedures. We do know crudely that one stimulus to bone formation is exercise of the part and that immobilization or reduction of blood supply is conducive to bone resorption. Certain general stimuli also bring about bone resorption—for example acidosis and parathyroid hormone. Efforts should be made to determine the fundamental stimulus which is active in bone resorption in these patients. If it could be found, we might eliminate it and hence prevent atrophy of disuse. This would be getting at the problem at its

source. Should such fundamental information become available, we might be able to eliminate the problem of stone formation in these patients, at least reduce the problem of stone formation to the same level of frequency as occurs in the population at large.

DR. HUGH JEWETT, Baltimore: Dr. Howard has stated that his studies have shown that urinary calcium is not increased by the addition of milk to the diet. However, milk is exceptionally rich in phosphorus. According to Dr. Fuller Albright of Boston, per gram of protein, milk contains three times as much phosphorus as muscle. Since the stones under discussion are practically always composed of calcium phosphate, should or should not milk be excluded from the diet of these patients because of its high phosphorus content?

CAPTAIN BORIS P. PETROFF: I should like to answer Colonel Gage about thrombophlebitis. There were 2 cases, 1 from overseas with a terrifically big thigh, the other with a swollen leg which was assumed to be thrombophlebitis. I am surprised that there has been no question of suprapubic cystotomies, because when these patients first came in with a suprapubic tube in them it was mainly on the suggestion of Major Elkins that they were changed from suprapubic to urethral drainage. Major Elkins did a firm bit of insisting. I was all for leaving the suprapubic tubes in, but Major Elkins said to go ahead with the removal of suprapubic tubes. We made the change, the first patient developed epididymitis, and Major Elkins said to let it stay in—that it wouldn't hurt him. He is one of our prize patients, voiding with an automatic reflex bladder. As to periurethral abscess, we end up with a fistula and, when the patient begins to void, the urine runs out over the floor like a watering can. This is a great problem to us, and I should like the visiting urologists to suggest some way of repairing this penoscrotal type of fistula.

MAJOR JAMES J. JOELSON: In answer to the question concerning renal stones in Negro soldiers, we have seen none but we have had very few Negro patients. The points raised by Dr. Howard are interesting and important. Flocks has shown, however, that a high calcium diet will increase the amount of calcium excreted in the urine. Also the phosphorus content of milk must be considered, and since most of these recumbency stones are calcium phosphate it would seem much wiser and safer to eliminate milk from the diet, or at least keep its intake at a reasonably low level. Although ammonium chloride may mobilize calcium from the bones, still in some cases a properly acid urine will cause a dissolution of the stones which have already formed. If the patient can be kept under proper observation, the use of this drug seems justified in an effort to obtain the very desirable result of dissolving the stones.

MAJOR FRANK C. HAMM: We have had no cases of stone in Negro patients included in the series referred to in the paper. I can recall only 3 instances of urinary stone in the Negro soldier. These instances were observed before our present survey was carried out. I do not know how many patients we have seen or what the ratio to the white patients has been. It is my belief that the relative absence of stones in Negro troops is due to a racial factor rather than to their acid ash diet, as the food in the Army is the same for all soldiers. Pulvertaft has observed an increase in calcium output following prolonged exposure to sunlight in recumbency cases, and he advises against excessive exposure to sunlight. These observations should be repeated. We should not adopt a policy of excluding heliotherapy from these patients. I cannot believe that a moderate amount of sunlight is harmful.

Surgical Treatment of Decubitus Ulcers

CAPTAIN DONALD E. BARKER, M. C., A. U. S.: Of the 21 patients in this series 10 had only 1 ulcer; 5 had 2 ulcers, 4 had 3 ulcers and 1 had 5 ulcers. The ulcers ranged in size from 1 by 2 inches to 6 by 8 inches, covering the entire area over the sacrum. Seven patients had ulcers over one or both hips. As soon as a definite line of demarcation became apparent, the necrotic tissue was dissected away with scissors. From that time until grafting the ulcers were dressed with either boric acid ointment, urea ointment or an emulsion made by mixing 4 cc. of penicillin in 1 ounce of petrolatum. The appearance of the ulcer was not affected greatly by the type

of ointment used. When the ulcers had a clean base the operations were done. No attempt was made to get the areas bacteriologically clean. Split thickness skin grafts $\frac{1}{16}$ inch in thickness were used in 16 cases. The granulating area was shaved down to a yellow base when possible and the graft sutured into place. In a number of cases the ulcer was so close to the bone that no incision of the granulation tissue was possible. In all of the cases wet dressings were used for four days after operation. The principal problem met here was the inability of the patients to remain in one position for any period. In the constant changing of position by the ward personnel the dressings were moved about and accounted for the loss in some grafts. One patient with five large sores was grafted three times without success. His daily protein loss from the sores was 50 Gm. a day, and there was reversal of the albumin-globulin ratio.

A total of 30 operations have been done to date. Sixteen of these were skin grafts and 7 primary closures, 2 by basket weaving and 5 by rotation of a flap. Of the 30 cases 19 are healed at the present time; 27 per cent of the ulcers have about 50 per cent closure, and of the 30 cases there were 3 complete failures. In the rotation flap and the primary closure series the results were better than those in which split grafts were done. This is probably due to the fact that the split skin grafts were used in large ulcers and also in cases in which the condition seemed too poor to permit extensive radical surgery. Of the primary closures and rotation flaps 80 per cent healed after the first operation.

The following types of closures are recommended: In large ulcers of the back; i. e. those measuring about 4 inches in diameter, and also in cases in which there is extreme debilitation, split thickness skin grafts are the method of choice. In small ulcers measuring from 1 to 3 inches over the back the method of choice is excision of the ulcer and closure at the time of operation. In ulcers of the hip, skin grafting is not recommended. Even in the smaller ulcers of the hip it is recommended that a rotation flap be done. In ulcers from 1 to 2 inches in diameter a rotation flap with primary closure of the donor area is the method of choice. In large ulcers a large rotation flap to the ulcer area with split thickness skin graft of the donor area should be used.

It is estimated that the time saved in these ulcers varies from six months to two years, and in some of the larger ulcer areas it is probably a life saving measure to use split thickness skin grafting. An ulcer about 1 inch in diameter may take six to nine months to heal, whereas ulcers of the back such as some shown in this series without surgery would probably not be healed after five years. I believe that the excision enclosure of even as small ulcers as three fourths of an inch in diameter that have penetrated to the subcutaneous tissue should be done.

Primary excision and closure of small ulcers of the back is the method of choice. In large back ulcers or in patients who are very poor risks surgically skin grafting is successful and the recommended method. In hip ulcers a rotation flap is a quick method of a permanent closure.

The Nutritional Aspects of the Care of the Paralyzed Patient

CAPTAIN HAROLD A. HARPER, Sn. C., A. U. S.: It is now well recognized that malnutrition may occur as a result of disease or injury. The majority of paralyzed patients have lost a considerable amount of weight, particularly in the atrophic paralyzed extremities. Many also present evidences of generalized emaciation. The nutritional deficiencies of these patients are due to a number of factors. On admission to hospitals in the zone of interior nearly all have large, oozing, decubitus ulcers which are a source of considerable loss of protein. Infection is a common complication, with the result that depletion of reserves is accelerated. It is most important, therefore, that immediate attention be directed to an evaluation of the state of nutrition of these patients and that methods for correction of the malnourished state and the maintenance of an optimum level of nutrition be instituted. Protein losses by exudation may be extremely large: up to 50 Gm. in some cases. The so-called toxic destruction of protein, which is a concomitant of disease or injury, may account for considerable loss and, together with the wear and tear quota, one may find that more than 150 Gm.

of protein a day will be necessary to achieve nitrogen balance. The underlying injury or pathologic process may decidedly influence the mechanisms responsible for blood and tissue protein synthesis. A study of the blood proteins of these patients frequently reveals increased globulin and decreased albumin levels. This may be the only objective evidence of protein malnutrition, but it is to be considered as indicative of extensive depletion of protein stores. Recent studies have indicated that there is a definite metabolic partition between the plasma and the rest of the body. It is stated that each gram loss of plasma protein is accompanied by a loss of about 30 Gm. of tissue protein. When regeneration takes place, only 3.5 per cent of the nitrogen retained is used to replenish serum albumin, while 96.5 per cent is allocated to replace tissue protein stores. This explains why large quantities of protein may produce relatively little improvement in plasma albumin levels.

To use a determination of the total plasma protein as a diagnostic aid for assay of the state of protein malnutrition, one must take into account two important factors. For under certain conditions a normal value will be reported when there is actually protein depletion. These factors are (1) the effect of dehydration and (2) the presence of decreased levels of albumin accompanied by an increased globulin. As plasma protein diminishes, the water retaining power of the blood is also decreased. Fluid is lost to the tissue spaces, and increased concentration of the plasma will occur with a consequent decrease in total plasma volume. Quantities of protein which would be low in a normal plasma volume would then appear normal or even elevated. Conversely, when the concentration of the serum albumin is raised there will be an increase in the plasma volume, averaging about 17 to 18 cc. per gram of albumin retained. One clinical study reported increases in plasma volume of 600, 800 and 900 cc. in patients receiving 50 Gm. of albumin. Therefore as one replenishes plasma protein stores there will be a shift in fluid balance so that, for temporary periods at least, an increasing plasma volume will have the effect of reducing the actual concentration of protein.

Again, one may find that total protein is normal but actually there is hypoalbuminemia which is masked by an increase in globulin. This is particularly true where there is chronic infection, most of the increase occurring in the gamma globulin fraction, rich in antibodies. To obviate these pitfalls, red cell counts and hematocrit determinations should be obtained simultaneously with the plasma albumin and globulin in order to estimate the probable degree of dehydration. Although much emphasis has been placed on albumin globulin ratios, the plasma albumin content is actually the significant factor involved.

Correction of nutritional deficiencies in these patients may be expected to enhance greatly the success of all aspects of their care. Healing of the decubitus ulcers will be favored, as will the success of grafting procedures. As the extensive losses of protein from this source are diminished, it will become progressively easier to restore and maintain nitrogen balance. The patient can be expected to combat more successfully the chronic infection to which he is exposed. The efficacy of chemotherapeutic agents will be enhanced and wound healing materially improved.

The basal diet of these patients can ordinarily be the regular high protein diet of the hospital if there is no obvious impairment in their ability to digest or assimilate it. If the diet is properly consumed, one can probably depend on a daily nutritional intake of about 2,800 calories and 100 Gm. of protein. A much larger daily intake of protein will often be necessary to compensate for the losses in exudates as well as those of normal and abnormal metabolism. Additional protein must be allowed for the synthesis and replenishing of body proteins. One should set a protein objective to be attained daily by these patients—possibly 150 to 175 Gm., or more if tolerated. The other components of the diet are depended on to supply as much energy as possible in order to spare protein to a maximum degree for use in anabolic reactions. It may be desirable to increase vitamin supplementation. In the presence of anemia most of the administered protein is diverted to the synthesis of hemoglobin and it is not until the anemia has been corrected that satisfactory tissue and plasma protein

regeneration will occur. In these situations the use of whole blood is of value. To correct an acute deficiency of plasma protein, especially where there is frank edema, the administration of plasma or plasma albumin is ideal. But, in a chronic hypoalbuminemia due to malnutrition, plasma is of value but may be disappointing. For every gram of plasma protein which remains in the blood possibly 30 Gm. is removed by the rest of the body. To supply 2,000 Gm. of protein for the entire body requires 30 liters of plasma (120 donors).

From a nutritional point of view it would seem more physiologic to supply good quality protein in a more economical and assimilable form. This can be achieved by the use of certain protein concentrates or hydrolysates, several of which are commercially available. Two are hydrolysates of casein, the protein of milk, and are available for both oral and intravenous use. A third is a mixture of wheat, beef, milk and yeast proteins, for oral use only. It is usually possible and desirable in all of these cases to confine alimentation to the oral route. In addition to the advantage of providing as normal a regimen as possible, one must consider the fact that individuals whose plasma protein levels are dangerously low cannot tolerate intravenous fluids with impunity. To administer 100 Gm. of protein, as a 5 per cent Amigen solution, for example, requires the introduction of 2 liters of fluid. Such a procedure will not be well tolerated if continued for some time.

It is advisable that patients requiring intensive nutritional care be recommended to the attention of one dietitian who will be specifically assigned to the task of supplying adequate nutrition in these cases.

DISCUSSION

LIEUTENANT COLONEL CONDUCT W. CUTLER, M. C., A. U. S.: Forty-five of 67 patients admitted to Cushing Hospital had bed sores. Two of the 67 had slight progression of their bed sores after admission. No patient has developed a bed sore following entry. The bed sores are characteristically multiple; thus there have been 130 decubitus ulcers in the 45 patients. Important considerations in treatment have been found to be constant and repeated turning of the patient every two hours day and night, the use of small kapok pillows to prevent local pressure on sensitive areas (supporting the chest and pelvis on pillows in a prone position makes for comfort and better breathing), keeping patients dry at all times, adequate nutrition and attention to avitaminoses and protein deficiencies. In local treatment various applications have been tried, including petrolatum gauze, penicillin jelly, granulated sugar and a preparation of concentrated red cells with penicillin and agar. Of these the granulated sugar has proved particularly effective in diminishing pyocyanus infection and slough. Epithelialization seems to be rather more rapid under this treatment. Cleansing of the wound and rapid development of granulations of a healthy character have followed the use of a paste composed of concentrated red blood cells thickened with agar and containing penicillin. Associated with this type of preparation, secondary closure has been used in 17 cases and has proved most satisfactory in deep penetrating bed sores measuring not more than 7 cm. in diameter over the sacrum and 5 cm. in diameter over the trochanter. Penicillin is given forty-eight hours preoperatively and twenty-one days postoperatively. The wound is cleansed with saline solution, the edge of the decubitus trimmed away with complete undermining of the entire skin and subcutaneous tissue over the sacrum and low back out to the flanks for a distance of 8 to 10 inches, superficial to the gluteus muscle. Closure of the circular defect is performed with tantalum 0.010 suture in two layers, one for the deep fascia and one for the skin. No drain is employed. The wound is filled with penicillin solution, and the same solution is injected through the suture line into the wound area twice a day for ten days. Stitches are left in place for twenty-one days. In trochanter decubitus the treatment is the same. Three layers are usually required in the suture, as the sore frequently extends through the fascia lata and the gluteus maximus fascia. These are closed separately from the subcutaneous and skin layers. A plastic extension is always necessary. When complete suture closure has

been effected there has been no case of reopening or breaking down. Slower healing occurred in those cases which could not be completely closed.

LIEUTENANT MARK A. JACOBS, M. C., A. U. S.: Most of these patients come to us in a poor state of nitrogen balance and in mild acidosis. They have a hypoproteinemia with a reversal of the normal albumin-globulin ratio, avitaminoses, calcium metabolic changes with the formation of renal and cystic calculi, infected kidneys and bladders, and necrotic skin ulcers. The skin ulcers were a large possible source of inanition and nitrogen imbalance. These decubitus ulcers varied in size and number but in all cases were infected and oozing. Through the use of cellulocotton dressings of these ulcers we were able to obtain sufficient material for our experiments. By covering these ulcers with the pads for twenty-four hours and then doing a micro-Kjeldahl determination on the material contained on the pads, we found that these ulcers did have an important bearing on the nitrogen balance, hypoproteinemia and albumin-globulin ratio. One patient with 5 ulcers was found to have a total protein loss from these of over 40 Gm. in twenty-four hours. A tremendous increase in protein intake is necessary to obtain a zero balance, much less achieve a positive one, since to this ulcer loss must be added nitrogen loss through the usual sources, such as urine, feces and perspiration. Also add to this the anorexia and one can see how our problem becomes increasingly difficult of solution. As infection from all sources was brought under control, the nitrogen balance gradually tended toward zero and the albumin-globulin ratio showed improvements, but maintenance of infection control was almost impossible. A partial solution to the problem was found in the use of skin graft coverings for the decubitus ulcers. Where and when this was done, the protein loss through these ulcers became negative. The patient tends toward and approaches a positive balance and the albumin-globulin ratio tends toward normalcy. We are attempting to clear up all sources of infection. But there still remains the question of how to get enough proteins, enough calories and enough vitamins into these patients.

Ambulation and Support

CAPTAIN J. E. CAMERON, M. C., A. U. S.: In the treatment of paraplegia we define ambulation as the ability to get about by means of braces and crutches proficiently enough to care for oneself at home; to carry out the necessities of ordinary life without help.

The following expected results justify the initiation of an early and vigorous program of ambulation for each patient with a spinal cord injury:

1. The morale factor: Any advance in the ability of these patients to get about either in a wheel chair or on crutches causes an immediate improvement in their general outlook on life, their appetite and their general health.

2. Therapeutic exercise: In our 70 cases, 49 are incomplete or recovering. In many cases the prognosis cannot be given, even after direct inspection of the lesion at the time of laminectomy, and it may be many months before any recovery takes place. It is in this group of cases (which in our series represents 70 per cent) that the very early initiation of a program of ambulation is of immeasurable benefit. This benefit is derived from the passive exercise obtained in the swinging movements of otherwise paralyzed lower extremities. No amount of artificial or assistive physical therapy can make up the equivalent of such exercise.

3. Neurologic changes: For some unexplainable reason weight bearing on the feet seems to overcome pronounced clonus and involuntary mass movements seen in recovering cord injuries.

4. Improvement in general nutritional vasomotor functions: The resumption of the upright position is a great benefit in the general bodily tone and cardiovascular status.

The program at the Newton D. Baker General Hospital consists of (1) exercises to strengthen the muscles of the upper extremities used in crutch walking, with particular attention to the triceps and muscles of the shoulder girdle; (2) braces, which are ordered on the patient while his bed sores

and bladder are being treated (in cord lesions with little or no function in the abdominal musculature a thoracopelvic girdle is necessary); (3) a walker (the standard army walker is used, with a crutch type arm support); (4) crutches. Patients with high lesions require prolonged and tedious instructions in the art of paralytic walking. Normal walking is a complicated process for any biped animal. The only phase of the normal gait seen in a paralytic patient is that which takes place as the non-weight bearing extremity is allowed to swing, like a pendulum, forward; the paralytic gait is therefore fundamentally a succession of alternating pendular movements. Propulsion is obtained by the tripod action of each of the two crutches and the braced lower half of the body. Such walking involves swinging the pelvis and lower extremity by either the thoracic cage or the abdominal musculature, the force being transmitted through the braces. Since the gluteus medius muscle is paralyzed, it is necessary that the patient lean far to one side in order to raise the opposite extremity off the ground. This makes for a grotesque overmovement at first, which requires long practice before it is eliminated.

Any patient with a cord lesion at or below the tenth dorsal vertebra should be got into braces promptly and without waiting for recovery of muscle function below the lesion. We can extend to such a patient the hope of ambulation with crutches provided his upper extremities are intact. Patients with cord lesions as high as the second dorsal (provided their upper extremities are intact) may with prolonged practice and instruction be able to get around in braces, but to these patients we give a more guarded prognosis. For those patients with high lesions unable to use the walker, we initiate a prompt wheelchair program. The simple change of posture and the additional exercise incurred in moving a wheelchair are a great benefit to the patient.

The question of amputation of the lower extremities for irrecoverable loss of function as in paraplegia has been raised. The Council on Physical Medicine of the American Medical Association advises that amputation be performed only if simple amputation will offer a better prognosis in terms of appearance, comfort and function and if a sufficient part of the extremity possesses enough useful function to work well in a prosthesis. Certainly few, if any, cases of paraplegia would meet these requirements unless complicated by extensive bone or vascular damage.

In summary, early initiation of a program of ambulation for paraplegic patients raises their morale. Physical therapy may overcome clonus and mass movements in partial lesions and improve the nutritional state and vasomotor tone. Such a program consists of exercises for the upper extremities, the early fitting of braces and supervised instruction in paralytic ambulation, starting in a walker and progressing to crutches.

The Daily Care of the Paralyzed Patient

LIEUTENANT COLONEL DAVID HENRY POER, M. C., A. U. S.: The days when the patient who had received a spinal cord injury with resulting paralysis was treated as a troublesome and hopeless invalid are definitely over. The men of the Army Medical Corps can point with pride to the fact that they have led the way in bringing about such a complete reversal of this attitude and action and that they have met the issue with all the resources of the medical profession. The basis for the everyday routine in caring for the paralyzed patient at the Newton D. Baker General Hospital, Martinsburg, W. Va., is the purposeful development of a strong patient-doctor relationship. All matters of every nature, all supervision and management is directly the responsibility of the one doctor-officer under whose care these patients are placed. All personnel responsible for the care of these patients work directly under his authority. He must be familiar with everything that is being done for his patients. This relationship becomes of inestimable value to the patient himself in that he finds that he has a firm post to tie to and to spring from on his road back to a reasonably satisfactory mode of living. The time and method by which the doctor establishes, builds up and cements this relationship are during the daily ward rounds. These must be regular and systematic, at least

once daily, including Sundays and holidays. Other rounds made in the evening have proved to be of immense value, since those hours are usually free from the hurry, bustle and rush of the average hospital day and it is during these periods that the patient learns that his doctor not only knows his problem but also knows the solution. The complexity of the problem of the paraplegic requires this unusually time consuming program, but it pays large dividends in a manner not to be obtained otherwise.

The most important member of the treatment team is the hospital corpsman or ward attendant. We have given these men and women special training in the handling and care of paralyzed persons. The duties of these attendants are chiefly concerned with the care of the bladder and bowel, changes in position of the patient and aid in ambulation. Assistance is also given in the changing of bed linen and mattresses and in feeding the patient. The use of special frames for turning the patient (Stryker) have not been found necessary when the attendants carry out their duties properly in shifting the areas of pressure on the body.

The next in this therapy group are the technicians, who carry out physical therapy, and all this work blends readily into a reconditioning program consisting of exercises that will give the individual the necessary massive shoulder girdle to substitute for leg motion. Special urologic technicians or male nurses carry out all but the simpler procedures necessary to keep the urinary tract free from infection. Brace makers, Red Cross social and recreational workers, librarians, education and vocational instructors are some of the many workers needed.

The nurse shares with the doctor the responsibility of carrying out the necessary details of treatment and must be his listening post and intelligence department to acquaint him with all information, to advise and to make suggestions as are needed in order to obtain the desired results. She must supervise the work of the attendants and technicians.

In addition to the recreational programs given by Red Cross personnel, attention must be paid to their religious needs. Chaplains pay daily visits, and effort is made to take the patient to the chapel services. Personal guidance and counsel are provided to take care of all legal and business matters as well as domestic problems, where adjustments must be made by wife, children and other family members. An educational program is set up to fit the needs of each individual, and this must fit into the vocational plans to provide a livelihood after discharge.

Since the original injury is to the spinal cord, it is with the neurosurgeon that the launching of the original plan must rest. The urologist has more actual daily contact with the patient until an automatic function of the bladder has been established and infection brought under control. The internist, especially the nutrition expert, has his important function, the results of which are hastened by successful plastic surgery by closure of the decubitus ulcers. The orthopedic and the general surgeon likewise have their part in the treatment of associated conditions or complications.

Nothing has been said about the field of research which has been opened by the study of the results of this type of injury. The control of decubitus ulcers has been partially solved by increase in our knowledge concerning protein and nitrogen metabolism, and attempts are being made to control or prevent infection in the urinary tract. The sulfonamide drugs and penicillin have been of inestimable value, but the problem of the gram-negative organisms remains. Further information concerning calcium metabolism is required, as well as all metabolic processes in paralyzed tissues. Good morale in a paraplegia ward can best be obtained by treating patients in groups and perhaps later in a specially constructed and equipped colony where they can become self supporting and by following the outline just given. This will convince the patient and his family that everything is being done to cure his immediate ailments, get him to walking again, develop a degree of bladder and bowel control, teach him a gainful occupation and discharge him promptly. After that the morale factor of the paraplegic becomes no factor whatever.

The Future of the Paraplegic

LIEUTENANT COLONEL CALLEB S. STONE, M. C., A. U. S.: We have learned much from our small group at Wakeman General Hospital with regard to the economic adjustment that will be necessary. It may be plainly stated that some of these patients, particularly the younger untrained and unmarried men, feel that the pension of \$150 a month plus the \$100 a month allowed for an attendant that will be paid on discharge from the Army will always be adequate to meet their needs; others are anxious to work because they need the additional income. In our small group there are 3 men who have been promised jobs by their old companies provided they are ambulatory in wheelchairs; 2 men come from families who own a business in which the soldier can be productively employed in a wheelchair. Further efforts to rehabilitate and reeducate the paraplegic is a responsibility that should be met because a reasonable percentage of them can, if rehabilitated, adequately return to gainful employment.

Domestic adjustment will be difficult. Obviously single men in this group will rarely marry unless they are picked up by some one seeking a meal ticket. Doubtless many of the married men will separate from their wives. Some of the married men who have children will not separate from their wives because of the children. In any event, this is purely a personal problem. The responsibility of a governmental agency could only go so far as to provide a man with the necessary physical reconditioning and training.

Since the subject given to me is "The Future of the Paraplegic" I may be justified in offering a plan for the care of the paralyzed soldier, based on observations with a small group of patients but a group which may well be considered a cross section of the total number of the paraplegic. It would seem pertinent to suggest that the Army create a center for the rehabilitation of the paraplegic. If an adequate number of beds could be made available and an adequate staff, it might well be that patients yet to sustain injury to the spinal cord could also be best treated during the early stages of their disability in such a center. The primary purpose, however, of a center for the rehabilitation of the paraplegic should be to accept patients after initial definitive care has been completed. One might estimate that the average stay in such a center would run from eight to twelve months. The purpose of such a center would be to complete the physical reconditioning of these men, equip them with the muscular development of the trunk and shoulder girdle so that they may become completely ambulatory in braces or wheelchair, so that they may withstand the strain of continued physical effort while seated, and to educate them so that they may become able to care for themselves in every respect; to give them vocational training suited to their ability, their past experience or to opportunities awaiting them or to give them the education and training necessary to open up for them new fields of endeavor for which they have talent or desire—fields of endeavor which in the past have not been available to them—and so to rehabilitate and reeducate them that they can return to a civilian status without being dependent the rest of their lives on institutional care, which at best does not give a person any reason or purpose for remaining alive.

Such a center should be placed in a suitable climate, one that permits outdoor activity pretty much the year round, where extremes of temperatures are not encountered.

Such a center should be housed in one story structures to permit easy access outdoors to men in wheelchairs or on crutches. The housing facilities should be fireproof unless they are all one story structures close to the ground. If a multiple story structure is used, it would of necessity require adequate elevator facilities. Such a center should be on the main line of a railroad in the community where adequate and suitable housing facilities are available for the many visitors who should come to patients of this type. The necessity for a work program might well demand that such a center be placed with reasonable proximity to industry and also somewhat removed from a locality where labor is superabundant.

Such a center would require adequate personnel, both in training and in quantity. Neurosurgeons, urologists, internists and a general surgeon would all be required in proportion to the number of beds occupied. In addition, properly trained

physical reconditioning men would be necessary, an adequate brace shop, a large physical therapy and occupational therapy department, nutrition officers and dietitians.

When one considers the vast number of questions raised by this group of patients the answers to which are unknown, it becomes obvious that such a center should have associated with it a comprehensive research program.

The key personnel referred to would necessarily be men with an interest in and an appreciation of the problem of the paraplegic. Above all, such a center would require sympathetic, imaginative and understanding direction from its commanding officer.

DISCUSSION

COLONEL ROBERT H. KENNEDY, M. C., A. U. S.: When we first received these patients, they came in rapidly and their morale was bad. Since the program was developed, the morale in the paraplegic ward is better than in any other ward in the hospital. I went on a two months mission last fall. When I left, the neurosurgical center had just been organized. On my return it had received about 600 patients and among these was a group of 39 paraplegic enlisted men and 2 officers. Their morale was bad, and it was hard to go into that ward. I went on a Christmas leave and found on my return that a young lieutenant had gone to the commanding officer a few days before Christmas and said "We've got 39 men over there in the paraplegic ward. Christmas is coming and many of these men have their families here. I don't know whether they'll be alive next Christmas but they're here this Christmas and I want every one of these men to have their families here for Christmas dinner." The first answer was "No." This ward officer was a first lieutenant who had been in the Army four months. He said "I demand that these men be allowed to have their families here for Christmas dinner. These men deserve it. They have given everything to their country. They deserve to have their families here and, damn it, they're coming to dinner." They had 140 in that ward Christmas day for dinner. The Red Cross arranged for bridge tables at each bedside, with candles, fancy table cloths, comfortable chairs. Enlisted men, Wacs and nurses from other wards volunteered to come over and help serve the dinner. It did a great deal for the hospital morale for this officer to insist on this being done. The most pleased person in the whole group was the commanding officer, who presided most graciously over the whole affair. When you need more rubber tubing, irrigating bottles or walkers and are told they cannot be obtained, there is no such answer. Every one should take the attitude that there is no such answer as "No" to their needs. The changing of personnel in the ward is the most difficult thing we have to deal with. The enlisted men, nurses and officers in charge should be left to continue in the same place. But don't forget that this is a terrific job that these people are doing and we have to caution the wardmaster and the nurses to let us know if they are feeling the strain. Some may stand it for six weeks, others six months. There has been little said about the dressing of wounds. It should be put in charge of some one person who will take an interest. The medical officer can't attend to all these cases and should make ordinary dressings the responsibility of some one nurse. I feel that patient officers sometimes do not get as good treatment as enlisted men. I believe that the officer paraplegic should be put in the paraplegic ward and see what the other men are doing. It is a big morale builder. I wonder if it would be possible to keep in the service certain men at each one of the neurosurgical centers who are paraplegic themselves, who have been kept in the service as discharged hospital patients and who can train these men and be a morale builder among them.

LIEUTENANT COLONEL THOMAS P. SHEARER, M. C., A. U. S.: There is little in the literature on the operative treatment of decubitus ulcer. At Halloran General Hospital Captain Croce, chief of general surgery, has devised a scheme for closing these ulcers by rotating full thickness grafts from adjacent areas. Our preoperative management seeks to obtain a cleanly granulating wound free from infection and sloughs with fixed edges showing signs of epithelial invasion. Some of these ulcers are 12 to 15 cm. wide and 10 to 12 cm. long. The

ulcer is excised, then curvilinear incisions are made on each side both above, along the iliac crest, and below into the buttock. The large flaps so outlined are raised from the gluteal fascia. By rotating these four flaps toward the middle of the defect and approximating them to one another the defect may be completely closed with a layer of skin and normal subcutaneous pad, which thus far has seemed capable of withstanding all the abuse of the normal skin of that area. We have used a fine silk technic throughout with 000000 black silk. We have had no experience with Thiersch grafts because we have felt that the treatment as outlined is universally applicable, although some of the larger ulcers at first had to be closed in two stages. Moreover, we have felt that the end result is more durable than that of split thickness grafts applied directly over the sacrum. Some of the latter have broken down repeatedly until we covered them with sliding full thickness grafts. We have come to conclude that operative wounds in these paraplegic patients will heal fully as well as they will in other young adults whether the wound lies in an anesthetic area or not. By the simple closure of the decubitus ulcer the nursing care is greatly reduced; the patient is ready for a more advanced program and his morale is greatly elevated.

COLONEL CLAUDE BECK, M. C., A. U. S.: What we have heard in this symposium should not be regarded as the last word. We are only at the threshold in the care of these patients and I don't think we are going to stop where this symposium ends today. I should like to have a picture of what happened to the group of paralyzed patients in the last war; to see graphs on the duration of life and the causes of death; to know how many of the patients were taken care of in the veterans' hospitals and how many were able to be taken care of at home. After they arrived at their homes I should like to know what they were able to do, how much care they needed, whether any of them were able to earn a livelihood; I should like to know something about the composite picture of experiences to date in this present war. I understand that there are about 1,000 paraplegic patients in this country at the present time and that there are also additional patients abroad. We ought to have a composite picture of the course these patients have taken up to the present time. We have all been favorably impressed by the progress that has been made in the care of these patients. The picture, impressive as it is, is not as good as I would like it to be. I am disappointed in the matter of ambulation. These patients really do not get around very well. If they were to be discharged to their homes, I am doubtful whether they would get around well enough to go out on the street. Colonel Gage and I have been wondering about the advisability of bilateral amputation of the legs. Could the patient ambulate himself better if he did not have his legs? I should estimate that the legs weigh 40 to 50 pounds. With complete transection of the cord, the legs are absolutely useless in ambulation. What they actually do is to elevate the center of gravity from the ground, a distance of about 4 feet; they act like a pair of stilts and the patient is in constant fear of falling. Should we not amputate the legs? If this should be done the patient could get around much better, he would have less weight to pull after him, he could sit on a platform which has wheels under it and ambulate himself by means of his arms and he could also get around in a small motor vehicle. I am aware of the fact that we are not attracted to this idea of leg amputation because the body is mutilated by this operation and we don't like to mutilate the body. If it weren't for this aspect of the problem, I think we would all agree that amputation should be done. It does seem to me that, if any individual desires to have his legs amputated, the operation should be done and the results recorded. Captain Cameron was asked to look up the literature and he told me that he was unable to find anything on this subject.

CAPTAIN JOSEPH J. MICHAELS, M. C., A. U. S.: To the soldier with a cord lesion the reality of his disability is very obvious. There is the objective fact of his being handicapped and failing in the ability to cope with life's situations. As a result it is natural to expect a certain amount of despondency and depression, which are consistent with the reality situation. With such a great degree of disability when neurotic com-

ponents develop, it is difficult to distinguish these subjective features because the objective aspects are so obvious. In contrast to the reaction of soldiers with paralysis, the soldiers presenting scars, deformities and even amputations, although somewhat handicapped, are not as severely affected from a reality standpoint. Here a much greater degree of neurotic factors is present, so that their reality situations may be considerably distorted. During the hospitalization of these patients they are surfeited with the attentions of many individuals. The suspicion arises that, just as the patient tries to deny the seriousness of his condition and avoids facing his reality, so those who deal with him similarly may conceal from themselves the seriousness of the problem. This statement is not to dampen the ardor of optimism that has been manifested but to arouse the necessity of perhaps being somewhat more neutral and questioning what we are doing. Captain Cameron has indicated to what extent the morale of these patients rises as they find themselves learning to walk. Doubtless this is comforting to the patient and offers him something to grasp at. It is my feeling that the patient's despondency is related not only to his inability to walk but to the whole general picture of helplessness. He is unable to carry on in many spheres. It is not only an impotence in walking but the realization of a pervasive impotence in the spheres of sex, work and society. Much effort has been expended in teaching the patient how to take care of himself. However, this teaching is more in the periphery of his personality, such as taking care of his bladder, bowels, muscles, appetite, eating, talking and doing things with his hands. Such activities are of course necessary, but it is believed that if the patient came to terms with the reality of his illness and settled this problem once and for all there would even be a greater participation in his attempts at helping himself. The doctor-patient relationship mentioned by Colonel Poer might be more fully utilized by permitting the patient to unburden himself as to just how he feels about himself in his paralyzed condition. What ambitions of his have been frustrated? What kind of a world will he be returning to? Who will be able to concern themselves with him as has been the case in the hospital? To what extent can we help him overcome the psychologic dependence that will have developed because of his actual physical dependence? He will have to learn to deal with his emotions in as independent a manner as he is learning to take care of his body. In regard to Colonel Beck's provocative question of the possibility of amputating the lower extremities, one must evaluate the relative gains of such a procedure over psychologic reactions to the loss of members of the body. Would we be adding another severe psychologic trauma to the severe physical trauma already present? How will the patient react to being regarded as a cripple? How will he feel about his appearance? In the Army there is a tendency to abbreviate, make short cuts and use symbols wherever possible. The very nature of war with its emergency features may call for such terminology. However, military expediency may unwittingly bring with it certain medical disadvantages. For example, to label a soldier an "amputee" to make us overlook the fact that there is always the soldier as a person with an amputation. We regard him as an amputated individual, concentrating on the amputated part when we call him an amputee. In like manner I should like to suggest that we always remember and refer to the patient who has a spinal cord injury with a resulting paralysis primarily as a patient with paralysis and not as a paralyzed patient.

LIEUTENANT COLONEL MARVIN P. KNIGHT, M. C., A. U. S.: One of my patients, a girl, had suffered from poliomyelitis since the age of 3, with the loss of the use of both legs. At the time I saw her the entire lower leg was some 18 to 22 inches in length. She walked with crutches very well. She could swing herself on a carrier a foot higher than her buttocks. I have seen other patients—one with an amputation of one leg above the knee, the other leg amputated below the knee. He walked very well and the only time you could tell that he had a prosthesis was by watching him go up and down a stairway. Prosthetic appliances have been so developed, especially since the application of aluminum, which makes them very light, that I would venture to say that a paralyzed patient

here who can walk 10 to 20 yards could walk a half mile following the application of a prosthesis correctly fitted. Of course, it is the problem of muscle transplants which have been carried out on poliomyelitis which aid a person to hold his body erect. With adequate muscle transplants from the abdomen and from the back, a patient's load would certainly be lessened following the removal of one or more extremities. The average patient can become ambulatory as long as two hinges are involved, but when a third hinge or the pelvis is encountered it is a very difficult problem.

CAPTAIN BORIS P. PETROFF: I was especially impressed by the new appliances to help patients help themselves. We have established bars in the latrines so that the men can help themselves on and off the commodes. In his paper Lieutenant Colonel Stone stated that patients were encouraged to take their own shower baths. This idea of a man taking a bath is a brand new one and we are going to try to emulate it as soon as possible. Captain Michaels has been a great help to us in the ward. We had 1 patient with complete negativism after bad news from home and only treatment by Captain Michaels snapped him out of it. Another problem is this question of sex. They can see, hear and feel and yet have no way of expressing the sex urge. Those who are married and have children are always glad to see their wives. Those who are not married and those who have no children are greatly frustrated. By certain remarks they make, the pictures they draw and the statues they make, you can see what is going on in the back of their minds. It is most important to have the neuropsychiatric service help them to adjust themselves to the outlook of the future without sex life.

Postmortem Findings in Six Cases of Traumatic Transverse Lesions of the Spinal Cord

CAPTAIN HENRY RAPPAPORT, M. C., A. U. S.: This is a report of 6 cases at Nichols General Hospital in which death occurred from complications of transverse lesions of the spinal cord. In 5 instances the fatal condition developed as a complication of the genitourinary tract infection, in the sixth from a complication of a deep sacral decubital ulcer.

Although these cases vary considerably as to their pathologic manifestations they have the following features in common: (1) the extreme emaciation at the time of death, (2) the severe secondary anemia and (3) a type of inflammation spreading by direct extension without respect for anatomic barriers such as fascias, periosteum, serosal membranes or capsules of visceral organs.

The type of inflammation found suggests strongly a pronounced decrease of the general and local resistance to infection. This lack of resistance is further evidenced by the type of organisms found in 3 of the cases in which pure cultures of gram negative bacilli were recovered from the postmortem blood. The same organisms were also found in the local lesions. In spite of the usual low pathogenicity of the organisms of the coli-aerogenes group they were apparently able to cause continued suppuration and septicemia in these debilitated patients. It has been shown that resistance to infection is considerably decreased in hypoproteinemia and that, once infection develops, the regeneration of blood protein is much more difficult. It is therefore suggested that the type of inflammation found in these hypoproteinemic patients was largely due to such lack of resistance, particularly lack of local tissue resistance. According to a recent publication the loss of tissue protein is much more severe than is indicated by the low plasma protein; the reduction to 1 Gm. in the circulating plasma is equivalent to a loss of 30 Gm. of body protein (Elman and others). It is suggested that the severe protein depletion of the tissues might account for their decreased resistance to infection. In all our cases anorexia developed sometime during the course of the disease, and the food intake was inadequate.

Although the number of cases presented is small, it seems to afford further evidence that there is a causal relationship between the degree of protein deficiency and the extent and severity of the inflammatory process. A vicious cycle is established whereby hypoproteinemia decreases resistance to infection, and, once infection develops, the regeneration of body proteins becomes more difficult.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Prefrontal Lobotomy in Schizophrenia.—Freeman and Watts maintain that schizophrenic patients are the most difficult to relieve by prefrontal lobotomy. The problem is much simpler with anxiety states, involutional depressions and obsessive tension states. Prefrontal lobotomy in schizophrenia is often unsuccessful when carried out as far forward as the plane of the coronal suture. The thinking patterns persist, and there is still enough of an emotional component to dominate the behavior. A lobotomy far enough posterior to the plane of the coronal suture to bring about such symptoms as reflex grasping and groping, with transitory Babinski sign and prolonged incontinence, will usually succeed in abolishing the emotional charge attached to the abnormal ideas, although at the expense of severe disability in the social adjustment. Every millimeter the subcortical incisions are placed posterior to the coronal suture prolongs the patient's convalescence. The authors are inclined to undertake prefrontal lobotomy in a chronic schizophrenic patient with the expectation of eventually performing a radical operation. If there is relatively good preservation of socially acceptable habits, they are inclined to incise the frontal white matter in the plane of the coronal suture, but with the understanding that a more extensive operation may have to be undertaken should the patient's condition remain unchanged. The authors have observed 50 schizophrenic patients over a period of two to seven years following prefrontal lobotomy. Slightly more than half of the patients are usefully occupied and less than 1 in 5 is institutionalized. While some chronic patients cannot be discharged from hospitals, their care is greatly simplified because of their new objective outlook on life and pleasure

in living. Prefrontal lobotomy is the procedure of last resort. This does not mean, however, that it should be delayed until emotional deterioration is well advanced.

Spontaneous Convulsions Following Electric Shock Therapy.—Pacella and Barrera say that of over 500 patients who received electric convulsive therapy 2 exhibited spontaneous generalized convulsions six and one half to eight weeks after termination of treatment. These 2 patients had never had seizures prior to treatment, nor were there epileptic manifestations in any of the family members. In both instances the brain wave tracings were abnormal prior to shock. It is concluded that spontaneous convulsions following convulsive therapy are prone to occur only in those patients who have latent convulsive tendencies as revealed by electroencephalograms. The suggestion is made that preshock electroencephalograms are particularly indicated for patients who give histories of previous convulsions in childhood or later life or who have family members exhibiting epileptic manifestations.

Electronarcosis in Schizophrenia.—Tietz and her associates say that a means to increase the benefit obtained by electroshock was sought in electronarcosis, which has been studied in experimental animals for the last forty years. This is a method of prolonged application of the electric current to the brain, causing a controlled state of unconsciousness preceded by a modified convulsion. Much preliminary work was carried out on animals before adapting electronarcosis to human subjects; more than 100 electronarcoses were induced in 9 patients without serious complications, and it was concluded that the method is without danger when cautiously applied. The present study is an evaluation of electronarcosis based on the treatment of 47 cases of schizophrenia. Over 1,000 treatments have been given without fatality or significant complications. The therapeutic effects of electronarcosis in a group of schizophrenic patients were superior to those expected of electroshock treatment and about the same as results expected from insulin shock therapy.

Active Immunization with Purified Somatic Antigens of Enteric Organisms.—Using an alcoholic precipitation technique, Morgan obtained a purified antigen from cultures of Eberthella typhosa which had been grown in synthetic medium, thereby avoiding contaminating materials which might have been derived from the usual complex culture substrates. The antigen produces a good immunogenic response in man in subcutaneous doses, although it is highly toxic for human beings when injected intravenously. Morgan made a comparative study of the purified somatic antigens of other organisms of this group and of triple typhoid (T. A. B.) bacterial vaccine for human immunization. He found that purified antigens prepared from E. typhosa, Salmonella paratyphi and Salmonella schottmuelleri cultivated in synthetic mediums produced less local and constitutional reactions than a triple typhoid bacterial vaccine when injected subcutaneously in man. Purified somatic antigens in

total dosage of 0.12 mg. for *E. typhosa*, 0.048 mg. for *S. paratyphi* and 0.048 for *S. schottmuelleri* produced higher titers of mouse protective antibody than did 2.5 cc. of a standard triple typhoid bacterial vaccine. These purified antigens possess the advantages of potency, stability and compactness.

Cutaneous Detergents.—Analysis of a survey of several thousand persons in various occupations disclosed that over 34 per cent believed that soap caused dryness, scaling, itching or burning or some combination of these symptoms. Guild states that soap and a variety of substitutes for soap do not fulfil all the qualifications of a desirable cutaneous detergent. Most of the available synthetic detergents are true sulfates and contain the hydrolyzable acid sulfate radical. Hence they release small quantities of sulfuric acid. This may be a contributing cause of the irritation produced by these sulfated compounds. Most of these synthetic agents contain sulfur joined directly to the oxygen atom and that, in turn, to a carbon atom, chemically represented as $R-O-SO_2-OH$. An ether sulfonate, however, contains the sulfur joined directly to a carbon atom, $R-SO_2-OH$. The latter compound cannot hydrolyze to produce sulfuric acid, as the bond $R-S$ is extremely strong. A detergent cream composed of petrolatum, wool fat, cholesterol, lactic acid and a sulfonated ether has been used for five years in private practice and in clinics of the Massachusetts General Hospital. The detergent lowers surface tension of water considerably more than does soap and is an active emulsifier of all types of oil. These properties make the cream about 40 per cent more active than soap. It is more rapid in action than soap and requires less water and less friction to produce suds. The cream, as well as the suds it generates, has a pH value of 5.5, which corresponds to that of the average normal skin. The cream is active under acid, alkaline and neutral conditions and when used with either hard or soft, cold or hot water. When used with sea water it is a good detergent and produces suds. The preparation is no more toxic than soap would be if accidentally ingested.

Colds in Industry.—Colds are responsible for more than one third of the total number of days lost in American industry. They cause a loss of 100 million working days each year. There is a definite pattern to the incidence of colds, with the

highest peak in December (or December-January) and a lesser peak in October. July is the month of the lowest incidence of colds. Sudden drops in temperature are followed by rises in the incidence and in the severity of colds. Both incidence and severity are much greater among office workers than among factory workers and greater among women than among men. A majority of the colds in women appeared at the time of the menstrual period. There is decreasing incidence of colds with increasing age. The severity of colds increases with age. There are fewer colds in air conditioned plants. The incidence of colds is highest in drafty places. More colds start on Monday than on any other day of the week. This is especially true of colds among men. Posture is an important factor in that the incidence and the severity of colds are lowest among those whose work necessitates walking about most of the time. Early therapy seems to be of greatest value.

Penicillin and Primary Suture in Acute Surgical Mastoiditis.—Johnson and his associates report their experience in treating 23 patients with acute surgical mastoiditis by primary closure of the wound and instillation of penicillin into the mastoid cavity. Seventeen patients showed complete cure after one course of treatment, while 6 remained well after a second course of penicillin. The recommended dose of the drug is 10,000 units every eight hours for four days (a total of 120,000 units). Local application of penicillin in the mastoid cavity through a ureteral catheter after mastoidectomy appears to be a feasible and practical procedure. When this drug is given in proper dosage, healing of the postaural wound and a dry external auditory canal usually are present on the fifth post-operative day. In cases in which aural discharge recurs, reinsection of the catheter and reinjection of penicillin for an appropriate period of time produce complete clearing of the discharge. Local treatment with penicillin seems preferable to the use of sulfonamide compounds for infections with *Staphylococcus aureus*, hemolytic streptococci and other organisms susceptible to the antibiotic agent because of the absence of any harmful toxic effects, the slight risk of sensitization and the increased speed of healing.

Salicylate Therapy in Rheumatic Fever.—Keith and Ross say that during the winter and early summer of 1944 an epidemic of streptococcal infection was prevalent among naval personnel. Cases of rheumatic fever appeared in the wake of this epidemic. Between February and the end of July 121 cases were admitted to the hospital with definite rheumatic fever. Of the 103 cases in the salicylate study, 70 were treated with a daily dose of 10 to 13.3 Gm. (150 to 200 grains) of sodium salicylate or acetylsalicylic acid. The drug was started on admission to the hospital and was given in five daily doses.

Each dose was accompanied with an equal quantity of sodium bicarbonate. In the control group of 33 cases 0 to 2 Gm. of salicylates was given daily. The salicylates were usually kept up for two to four weeks after the sedimentation rate was normal. Plasma salicylate levels were determined on a limited group. Oral administration of 13.3 Gm. (200 grains) of sodium salicylate with an equal quantity of sodium bicarbonate produced an average blood level of 31 mg. per hundred cubic centimeters. Ten Gm. (150 grains) of sodium salicylate with sodium bicarbonate produced a blood level averaging 27 mg. per hundred cubic centimeters. Such levels are sufficient to control joint symptoms, keep the temperature down and reduce the pulse rate. The sedimentation rate returned to normal in an average of four weeks. The incidence of heart disease was approximately the same in the high salicylate group as in the low salicylate group. Ten per cent of the rheumatic patients who entered the hospital with normal hearts developed rheumatic heart disease. Nausea, vomiting and tinnitus are much more common early in the administration of salicylates than after the patient has been receiving the drug for several days. These symptoms are not usually sufficient cause for stopping treatment. There was no evidence of kidney damage in this series.

Prevention of Acute Rheumatic Fever.—Fullerton says that in the city of New York in 1938 there were 1,105 reported deaths from rheumatic fever and rheumatic heart disease, whereas from six other common childhood diseases, namely whooping cough, diphtheria, measles, scarlet fever, cerebrospinal fever and infantile paralysis, there were only 247 deaths reported. There were five times as many deaths from rheumatic fever as from a combination of the six common childhood diseases. With the advent of the sulfonamides a practical method for the prevention of hemolytic streptococcal infections presented itself. Numerous investigators have administered since 1936 daily doses of sulfanilamide and latterly sulfadiazine to patients who had rheumatic fever. In the eight year period 815 rheumatic patients have been given this therapy, and only 8, or less than 1 per cent, have developed rheumatic fever, while the incidence among control groups ranged from 10 to 35 per cent. The value of this prophylactic measure has received tremendous impetus by its adoption and wholesale use in the U. S. Navy. In the latter part of the winter of 1943, 250,000 men were placed on daily doses of 0.5 Gm. of sulfadiazine twice daily, while another quarter of a million men were used as controls. During this period hospitalization for severe respiratory diseases was reduced 80 to 90 per cent, streptococcal infections were reduced 85 per cent and the incidence of acute rheumatic fever dropped so that for every 14 cases in the control group there was only 1 case in the treated group. The greatest hope in the prevention lies in the adequate and prolonged prophylactic use of salicylates during a rheumatic attack, to be followed immediately by prolonged prophylactic use of sulfadiazine.

Penicillin in Ludwig's Angina.—Bean and MacKenzie have treated Ludwig's angina with penicillin since 1944. At all times they have a tracheotomy set available, so that, if no improvement was noted in the first twenty-four hours, or if the progress of the disease warrants it, they are prepared to carry out surgical drainage without delay. Early surgery has not been necessary in the cases treated so far. Penicillin will control the infection in the early stages of Ludwig's angina in a high percentage of cases and will greatly reduce the number requiring early surgery.

Congenital Alkalosis with Diarrhea.—Severe diarrhea causes wastage of all the gastrointestinal secretions. The secretions which enter the intestine contain more of sodium than of chloride, and their total volume is several times larger than the volume of gastric juice. Diarrheal stools contain a larger quantity of sodium than of chloride. Diarrhea would not be expected to cause recession of chloride in the plasma with resulting alkalosis. Actually, in severe diarrheal disease, unless vomiting is a prominent feature, reaction change in extracellular fluid has been found to be in the direction of acidosis. Gamble and his associates report the case of an infant who disobeyed these simple and apparently axiomatic rules for diarrheal disease. He was 14 months of age when he entered the hospital. His affliction was a voluminous watery diarrhea which began directly after birth and had steadily continued. There was no evidence of impairment of gastric function. A large intake of milk supplemented by various other suitable articles of food was accepted without vomiting. Measurements of plasma chloride revealed persistently low values. The bicarbonate concentration was greatly extended beyond its normal value, and plasma p_{H} was increased. Observations on this infant indicate, but do not identify, an intrinsic defect in the control of electrolyte distribution in the body fluids.

Congenital Alkalosis with Diarrhea.—Darrow reports a case which is almost identical with that described by Gamble. The patient showed intractable watery diarrhea from birth to the age of 2 years 11 months. The stools were acid, contained considerable amounts of sodium, of chloride and at times of potassium. The alkaline urine contained no chloride, little sodium and variable amounts of potassium. Stool chloride was always greater than stool sodium and stool water greater than urine water. Absorption of nitrogen, fat, carbohydrate, phosphorus and calcium was essentially normal. The boy grew slowly and was subject to frequent exacerbations of the diarrhea accompanied by signs and symptoms of dehydration. The blood serum showed extreme alkalosis. Occasionally, serum potassium was low but usually was normal. Usually no signs of tetany

were present, but tetanic convulsions occurred once and carpopedal spasm occasionally. Metabolic data show that as chloride is lost more rapidly than sodium, extracellular sodium is transferred into intracellular fluids and approximately equivalent amounts of potassium are released from the cells and excreted. Similarly, when dehydration is treated with sodium chloride and potassium chloride, insufficient sodium is retained to account for the expansion of extracellular chloride but retention of potassium accounts for the release of sufficient sodium from cells to replace the deficit of extracellular sodium and to explain the changes in concentration of extracellular electrolytes. Darrow shows that the only striking difference between his observations and those of Gamble are the increased volume of stools which Gamble found when sodium chloride was added to the food. It is probable that Gamble's patient suffered at all times from a variable degree of potassium deficit. It seems likely that correction of severe alkalosis by administration of sodium chloride cannot be entirely successful as long as a deficit of potassium persists. Such a hypothesis may account for the difference in reaction of the 2 cases to treatment with sodium chloride.

Thiouracil Levels in Serum and Urine.—Paschkis and his co-workers studied the concentration of thiouracil in the blood and excretion in the urine following its administration in therapeutic doses to human subjects. They found a modification of Chesley's procedure for determination of thiourea more satisfactory for thiouracil than methods previously described. When administered orally, thiouracil is absorbed rapidly and is excreted in the urine rapidly. Absorption from the rectum is relatively poor and apparently inadequate for therapeutic purposes. Thiouracil is present in the erythrocytes and plasma in approximately the same concentration. It can be removed from the serum by dialysis and is therefore either in a free state or only loosely bound to protein. A more constant level is maintained when small quantities are given at frequent intervals during the day than when a single large dose is administered. Unless a large dose is given in the evening, the concentration falls during the night to practically imperceptible levels in the morning.

Rubella Cataract.—DeRoeth and Greene report 2 cases of congenital cataract in infants. In addition, 1 baby had microcephaly and microphthalmos and the other had a congenital heart lesion. The authors think that the cataracts should be extracted. The Australian committee pointed out that avian and mammalian embryonic tissues are more susceptible to infection than the adult tissues. This is the basis of Goodpasture's virus culture technic. The human embryo possibly possesses the same susceptibility to infection. The virus of German measles may pass the chorionic villi more readily than bacteria before a placental barrier has been developed. The Australian committee made the following suggestions: Expose all young girls to rubella; try to isolate the virus and prepare a vaccine against the disease; study the effect of convalescent serum to be used on the pregnant mother in case she had no rubella before. The question comes up whether therapeutic abortion is indicated if the disease is contracted in the first three months of pregnancy.

Susceptibility to Poliomyelitis.—Persons exposed to poliomyelitis may react quite differently, some developing constitutional symptoms with paralysis while others harbor the virus but show no symptoms. The cause for this difference is unknown, as is the actual reason for the common occurrence of virus neutralizing antibodies in serums collected from the general population. Approximately 70 per cent of poliomyelitis patients develop antibodies slowly, if at all, following a recognizable attack. If this is an inherited characteristic, it is pos-

sible that the fathers and mothers of patients with the paralytic form of poliomyelitis might be found to show a higher incidence of non-neutralizing serums than would persons of corresponding age from the general population. The serums for a determination of this point were collected from 42 mothers and 27 fathers of hospitalized paralytic poliomyelitis patients in North Carolina during the 1944 outbreak. When tested with the Lansing strain of poliomyelitis virus in white mice, the serums from 39 mothers neutralized the virus, 3 partially neutralized it and none were negative. Among serums from 27 fathers, 23 neutralized it, 3 partially neutralized it and 1 was negative. These results give no indication that paralytic poliomyelitis is more apt to occur among those whose parents do not readily produce circulating antibodies against the virus.

Use of Protein Digest Intravenously Following Surgical Procedures.—Davis reviews observations on the use of protein digest (amigen) in 203 surgical patients. At two hospitals amigen was given intravenously to most of the patients until they were able to take a soft diet by mouth. In another hospital Davis used no amigen but glucose and isotonic solution of sodium chloride as a control. In four groups of patients the favorable results of protein digest intravenously were especially noticeable, because a longer time elapsed before the patients were able to resume eating. They were given 1 liter of amigen twice a day until it was safe to begin mouth feedings. They maintained their strength and well being, and they did not develop edema. There was no need to give food by mouth until peritonitis had subsided and until bowel resections had quite healed. These four groups of patients included those with peritonitis, intestinal obstruction and gastric resections and those who had undergone colostomy mainly for carcinoma. The author advocates the intravenous use of protein digest following major surgery as a routine measure until such time as patients are able to take adequate nourishment by mouth.

Disarticulation of the Innominate Bone for Malignant Tumors.—Sugarbaker and Ackerman state that 99 patients have been operated on for tumors of bone or soft parts in the region of the upper femur or pelvis. Although an overall mortality of 28 per cent exists, that of the first forty year period was 56 per cent but during the past ten years it has dropped to 14 per cent. This drop has been largely due to improvement in the treatment of shock, which has been the primary complication of this operation. Of 45 patients surviving operation and followed for from one to five or more years, 21 remained clinically well and 24 died. The deformity, although considerable, is borne gratefully by these patients, who have become convinced that there remains no hope of cure. Far too few patients have received the benefit of radical operation. Advantages of wide resection have not been sufficiently exploited, particularly as regards partial or incomplete removal of the innominate bone when that bone itself represents the site of the tumor. With more adequate control of the mortality, patients will be selected less on the basis of age and more on the basis of the pathology of the tumor. Consideration of these factors will favorably influence the prognosis in sarcomas of the upper thigh and pelvic parietes.

Dicumarol in Postoperative Thrombophlebitis and Phlebothrombosis.—In probably 95 per cent of all cases postoperative pulmonary emboli which terminate fatally have their origin in thrombosis of the veins of the lower extremities. Both the incidence and the causation of postoperative thrombi are still matters of debate, but wherever the condition has been properly studied the incidence has always been found to be much higher than is believed. The incidence of postoperative thrombosis is related to the proportion of necropsies secured. For the past five years Parsons has been able to obtain necropsies in about 75 per cent of all fatal cases in his surgical service, and he has observed a relatively high incidence of pulmonary embolism and of antecedent venous thrombosis. The complication is most often observed after surgery, particularly on the pelvic organs. A nonpelvic origin is not infrequent, and surgery does not necessarily precede the development of pulmonary embolism. Thrombosis should be borne in mind as a possibility following any operative procedure and should be immediately presumed to exist if several days after operation there is unexpected or unexplained low grade fever or if there is tenderness in the calf of the leg on dorsiflexion of the foot (Homans' sign). When thrombosis or thrombophlebitis has been diagnosed or is seriously suspected, exploration of the femoral vein is a wise precaution. If pulmonary infarction has developed, it should be carried out without delay. With this treatment should be combined the administration of dicumarol, which is also a prophylactic measure; but dicumarol should never be employed without adequate control in the form of daily estimations of the plasma prothrombin time. If the plasma prothrombin time becomes dangerously lengthened, the administration of a vitamin K preparation or transfusion is indicated.

Hepatitis in a Diabetic Clinic.—Droller says that from January 1943 to January 1945 63 diabetic patients attending the clinic at the Royal Hospital in Sheffield were diagnosed as suffering from hepatitis. This clinic supervises approximately 450 patients. Anorexia, loss of weight and vomiting were the symptoms most frequently encountered in the patients with hepatitis. Tingling of fingers and neck rigidity may have been early neurologic manifestations. Owing to the sudden disturbance of the carbohydrate metabolism, immediate complications occurred in a number of patients. Insulin had to be increased and the diets altered. Another complication was acute atrophy of the liver, which caused the death of 2 of the patients. Delayed complications occurred in 8 patients, of whom 2 died of cirrhosis; the remaining 6 are in various stages of ill health. The epidemic occurred at a time of a high incidence of the

disease among the general population. It appears that both contact and syringe transmission occurred. There was queuing for weighing and bleeding. As the blood was collected in syringes which were not boiled, it is possible that small amounts of infective material might contaminate the needles. In view of the possibility that infected syringes were the cause of the epidemic, all routine blood letting was stopped after Sept. 1, 1944 and bleeding was done only in special cases. Since then, although the technic of blood drawing has not been changed, only 1 case has appeared after an interval of ninety-three days. With the abolition of routine blood letting, overcrowding has diminished and with it droplet infection.

Gas Gangrene and Vascularization of Muscles.—Power reports 20 cases of gangrene encountered among 6,000 wounded in a general hospital during the fighting in Normandy. Adequate notes are available on 16 of these 20 cases. Three factors are essential for the establishment of gas gangrene—the presence of pathogenic clostridia, an adequate mass of ischemic or necrotic muscle and delayed or faulty surgery. Ischemic or necrotic muscle is essential for the establishment of gas gangrene. If a small piece of shell passes through the thigh causing no arterial damage, gas gangrene will not develop; natural resources can cope with such damage. If a similar piece of shell passing through the thigh should strike an artery, muscles are rendered ischemic and form a suitable pabulum for micro-organisms. If clostridia are present in such a wound, gas gangrene will develop. Of the 16 cases under review, 14 occurred in the lower limb and 2 in the upper. This is accounted for by the more abundant arterial anastomosis of the arm and by the relative vulnerability of the leg owing to its greater mass. The author differentiates between massive gas gangrene resulting from damage to the main artery of a limb and localized gas gangrene resulting from laceration of muscular branches. There were two deaths, both resulting from gas gangrene following injury to the popliteal artery. The distribution of clostridia is widespread. They can be grown almost without fail from the battle dress. There still exists a fallacious belief that direct contact with the soil is the chief causal factor of gas gangrene. The Cutler and Sandusky findings contradict this view. The clothing is the important vehicle, especially the battle dress, which is largely composed of wool. In the desert warfare 30 per cent of all wounds contained the organism of gas gangrene, yet only 1 per cent of those so contaminated developed anaerobic myositis. In only 0.33 per cent of all wounds has arterial damage been inflicted and a sufficient amount of ischemic muscle produced on which the clostridia can multiply. The elimination of gas gangrene can come only from early and efficient surgery.

Primary Atypical Pneumonia Associated with Malaria.—Fleming and his associates report 112 cases treated in a military hospital in Italy. In most of the cases the onset was acute, and a high intermittent fever was present for an average of eight days. There was considerable debility, requiring from four to six weeks of convalescence, so that the majority of

these men were off duty for about eight weeks. Many of the patients were admitted during a period when there was a heavy incidence of malaria. About one third had the typical lung lesion in association with malaria. The presence of malaria had no influence on the period of pyrexia. The authors think that if they had not been aware of the prevalence of atypical pneumonia many of the malaria infected cases might, from physical signs alone, have been assumed to be merely associated bronchitis of malarial origin. Several cases presented an acute onset resembling malaria, and the diagnosis became clear only as the illness progressed unaffected by quinine therapy. There was no evidence that the association of atypical pneumonia and malaria was other than fortuitous. Sulfathiazole and sulapyridine had no effect on the course of the illness, but the authors ascribe the absence of complications to their routine use. There was no indication that they had any toxic effect on the polymorphonuclear leukocytes, and when used in combination with full doses of quinine, in the malaria cases, no adverse effect was noted.

Adrenalectomy in Paranoid Psychosis.—Allen and Broster say that a special study of adrenal disease has been made at Charing Cross Hospital since Broster performed an adrenalectomy on a patient with sexual precocity over fifteen years ago. It was noted that women with virilism were often abnormal and sometimes psychotic. Broster's publication on this problem attracted the attention of Gillespie, who discovered a woman with a severe schizophrenic paranoid psychosis combined with adrenogenital virilism. Following the removal of one adrenal she made a complete recovery. The authors present a similar case in which adrenalectomy was performed. This is the sixth case in which adrenogenital virilism has been combined with a psychosis. The response to adrenalectomy was similar to the one in the previous case.

Adrenalectomy in Hypertrichosis with Mental Changes.—Greene and his associates report the case of a woman aged 25 who had hypertrichosis associated with mental changes, which gradually resolved after adrenalectomy. The psychologic changes preceded the external physical changes. When first seen she was drifting into a tense hypochondriacal state. The removal of most of the causes of her anxiety did not bring about her recovery. Only after operation was she set on the road to recovery.

Amebiasis and Blackwater Fever.—McGuire has observed during the past twelve years 33 cases of blackwater fever in Bengal Dooars, where malaria is hyperendemic. The history of these cases was always the same, namely repeated attacks of malaria which were controlled by quinine, then suddenly the development of blackwater fever during one of these attacks after taking quinine. A popular view among the medical practitioners in the Dooars is that the causation of blackwater fever has something to do with the liver. Some workers recognize a preblackwater stage, which is characterized by an enlarged and tender liver. Krishnan and Pai concluded that liver damage and altered metabolism are factors in the etiology of the disease. McGuire was struck by the observation that among his 33 cases of blackwater fever there were 21, or 63.6 per cent, with the clinical signs of amebiasis. A tender and thickened cecum and ascending colon and an enlarged and tender liver

were present. Microscopic examinations of the stools showed *Endameba histolytica*. Though clinical signs of amebiasis were present in 9 cases, no protozoa were found. It is possible that the amebiasis in his series is a coincidence, but in view of the work of Krishnan and Pai it is also possible that amebic hepatitis may in some cases cause liver damage of a type that will help in the production of the biochemical blood changes reported by them, especially when these patients have a superimposed malarial infection. Quinine may cause further deterioration and act as an immediate excitant. The exciting cause in all the author's cases of blackwater fever was quinine. In no case did blackwater fever recur after atabrine.

Hypoplasia of Uterus and Spasmodic Dysmenorrhea.

According to Jeffcoate and Lerer dysmenorrhea is related to contracture of the uterus. The difference between painful and painless contractions lies in their character rather than their strength. The pattern of uterine motility causing pain during menstruation is unknown, but the view which supposes incoordination of different areas of the uterus, or disturbed polarity of the uterus, has still to be disproved. The theory which supposes uterine hypoplasia as the cause of the abnormal uterine contractions, and the evidence on which it is based, are critically examined in the light of what is known about the development of the uterus. An analysis of the histories of 829 patients suffering from spasmodic dysmenorrhea shows that not more than 27 patients had signs of uterine hypoplasia. The age at the menarche was usually within normal limits. Scanty and infrequent menstruation was exceptional, and most women had a regular cycle. Endometrial studies showed that the histologic phase generally agreed with the time of the menstrual cycle. Painful menstruation is usually ovular in type. Of 457 patients, some had minor malformations of the uterus; but these faults are not accepted as an indication of hypoplasia. The existence of an interval between the menarche and the onset of dysmenorrhea in a large percentage of cases is confirmed. This in itself is evidence against the hypoplasia theory. An analysis of a second series of 86 patients, all of whom had a hypoplastic or atrophic uterus, shows that of the 28 women who were menstruating only 1 had dysmenorrhea of an incapacitating degree. The value of estrogen therapy in spasmodic dysmenorrhea is open to question. If it gives relief, it does not necessarily do so by overcoming hypoplasia. The evidence is insufficient to prove or disprove the hypoplasia theory of dysmenorrhea, and it will remain so as long as the pathology of uterine hypoplasia is in doubt.

Vitamin B₁ Deficiency and Pregnancy Toxemias.—King and Ride say that there was a striking increase in the incidence of beriberi in Hong Kong during the years 1939, 1940 and 1941. An almost parallel increase was observed in pregnancy toxemias,

particularly eclampsia and preeclampsia, the toxemia rate rising from 3.45 per cent during the preceding three years to 7.82 per cent during the three years under review. Some correlation seems possible. It was found that of 371 pregnant women with beriberi 252 had pregnancy toxemia. The diagnosis of beriberi and pregnancy toxemia was supported by clinical and laboratory findings. Significantly high readings of the pyruvic acid content of the blood were obtained in the great majority of cases. In women with toxemia and beriberi the prognosis was considerably more grave than in cases of toxemia without frank signs of beriberi. This was particularly seen in the eclampsia cases, in which a mortality rate of 38.8 per cent was found in 36 cases complicated by beriberi as opposed to 11.6 per cent in 43 uncomplicated cases. It is suggested that the primary factor responsible for the heavy increase in pregnancy toxemia during the years under review was vitamin B₁ deficiency. Prophylaxis and/or active treatment by the exhibition of adequate amounts of vitamin B₁, whether in the form of a vitamin rich diet or as thiamine medication, is suggested as perhaps the most important single measure in dealing with pregnancy toxemia.

Mononucleosis from Benzene.—Mazel and his co-workers report the case of a youth aged 19 who had worked in a shoe factory and for the last year worked with a paste containing benzene. He complained of growing lassitude and mild dyspnea on exertion. Examination of the blood revealed severe leuko-

cytosis, at first a pure lymphocytosis and later a lymphomonocytosis with a plasmocytic tendency, giving a picture comparable to that of lymphomonocytic angina. This syndrome is accompanied by a mild impairment of the erythrocytic series with passage of few erythroblasts into the blood. The authors were unable to determine the duration of the process, as the discovery was accidental. It disappeared several weeks after the patient was removed from contact with benzene. Similar cases have been observed and reports published by other observers. These cases of mononucleosis induced by benzene have in common accidental discovery and cure after the patient is removed from the toxic atmosphere and given rest, and the hematologic syndrome is characterized by a mononucleosis.

Evolution of Human Telencephalon During First Four Months of Embryonal Life. Madeleine Friant.—p. 7.

Infiltration of Lumbar Sympathetic During Childbirth.

—Pigeaud employed infiltration of the lumbar sympathetic in the course of labor in 150 deliveries. Each infiltration consisted of 40 cc. of a 1:1,000 solution of nupercaine. For some time he made bilateral infiltrations at the level of the third to fourth lumbar vertebrae; then he made unilateral infiltrations on the left side from the second to the third lumbar vertebrae; with this method a painful zone sometimes persisted on the right side. With the bilateral infiltration complete analgesia is almost always obtained. Infiltration of the lumbar sympathetic of a woman in labor during the period of dilatation effects immediately or after several minutes the disappearance of pain for from one to two hours, or for seventy-five minutes on the average. Clinical observations and the graphic registrations showed that labor followed its usual course during the analgesic period. All infants were born alive. Infiltration of the lumbar sympathetic suppresses the severe pains which accompany the end of the period of dilatation.

Total Congenital Hereditary Alopecia. H. Lundbäck.—p. 189.

Rubber Products as Cause of Eczema.—A systematic investigation at the department of dermatology of the Finsen Institute, Copenhagen, showed that eczema caused by rubber is of rather widespread occurrence and not confined to certain occupations as previously supposed. Of the 80 reported cases, representing about 2 per cent of the cases of hypersensitivity eczema, only 25 were occupational. Rubber footwear and articles of clothing were the dominating causes of the eczema (about 74 per cent). Eruptions on the feet caused by rubber were in most cases difficult to differentiate from mycotic eczema. Etiologically the rubber itself was subordinate in relation to the accelerator agents used in manufacture. Of these mercaptobenzothiazole was the most frequent cause of sensitization. The prophylaxis of rubber eczema is sometimes difficult on account of the widespread use of rubber, its indispensability in certain garments and the penetration of the accelerator agents. Cold-vulcanized rubber can often be tolerated in cases in which there is only accelerator hypersensitivity.

Photosensitization Due to Handling of Parsnips.—Starck reports that in May 1943 a woman aged 43 applied to the dermatologic department complaining of an unusual looking skin change on her hands. She had been working in a cold storage room and for three weeks had been preparing parsnips. The change was most pronounced on her left hand. It involved only the dorsal side of the hands and a sharp, oblique demar-

cation line crossed the forearm, just where the sleeve ended. In the course of the following days 12 other patients arrived with similar symptoms. All 13 patients had been working in a factory which produced dried vegetables. Investigations revealed that the dermatitis was due to sensitization to light caused by work with parsnips. The author demonstrated in experiments that the parsnip root contains some substance liable to render the skin sensitive to a certain kind of radiation, that the sensitivity will remain for some time after the exposure to the plant and that the juice of the parsnip has not in itself any perceptible irritating influence on the skin.

Eosinophilic Granuloma of Bone.—Engelbreth-Holm and his associates review the early descriptions of eosinophilic granuloma of bone. This is a painful tumor of a bone, most often of a membranous bone, which usually develops in a child or young person. Roentgenography reveals a solitary, sharply defined defect in the bone, sometimes with swelling of the corresponding soft part. Microscopic study discloses a granuloma made up of reticular cells with numerous eosinophilic leukocytes, sometimes also giant cells of the osteoclastic type. The blood and sternal bone marrow may show a moderate eosinophilia. The differential diagnosis must take into account osteomyelitis, Ewing's sarcoma, bone cyst and Schüller Christian's disease. The authors observed eosinophilic granuloma of bone in 5 children between 2 and 9 years of age. They observed transitions from solitary eosinophilic granuloma through cases with several osseous foci to a generalized case with innumerable foci in the bone system together with diabetes insipidus, disturbance of growth and roentgenographic changes in the lungs. In several cases in which the disease commenced as a solitary granuloma, continued observation has revealed additional foci, so that in the cases observed by the authors the number of foci increased with the length of the observation period. Morphologically transitions were demonstrated from the lipid-free eosinophilic granuloma through granuloma with beginning lipid phagocytosis with Touton cells to entirely xanthomatous tissue. The authors conclude that the concept of eosinophilic granuloma can no longer be regarded as a nosologic entity but has to be considered a not altogether infrequent clinical monosymptomatic form of Schüller Christian's disease that often heals without becoming generalized.

Acoustic Theory of Percussion.—Bárány discusses the relations between the acoustic properties of the thorax, the Fourier spectrum of the percussion impact and the loudness spectrum of the resulting percussion sound. The importance of matching the Fourier spectrum of the impact to the acoustics of the thorax is pointed out.

Pathogenesis of Pernicious Tapeworm Anemia.—Tötterman found that an alcohol extract of tapeworm, when administered parenterally to 2 persons who had suffered from pernicious tapeworm anemia, resulted in an impairment of the blood picture, which subsided again spontaneously when the preparation was discontinued. Some local and general symptoms were observed. A control person did not show any changes; 2 others showed a passing decline in the blood picture, which improved, however, even though the preparation was continued. According to the author, these results support the conception that an increased sensitivity to tapeworm poison assumes an important role in the pathogenesis of tapeworm anemia.

*Disk Degeneration in Lumbar Region. E. Severin.—p. 1393.

Disk Degeneration in Lumbar Region.—Frequent disturbances of more or less pronounced sciatic type which occur in cases with disk degeneration in the lumbar region can be explained partly by disk protrusion, partly by the occurrence of disk prolapse. Severin's study of 210 cases in 1939-1941 showed that, while clinical examination can give useful indications, definite diagnosis depended on roentgen examination. There were disturbances mainly attributable to degeneration of an intravertebral disk in 221 patients treated in the Orthopedic Clinic, Stockholm, in 1943.

Electroencephalography in Epilepsy. T. Sison Frey.—p. 1647.

Sulfathiazole Filling and Primary Suture in Mastoidectomy.—In treating 80 patients Kjær and Kettel used sulfathiazole filling 101 times in the cavity with primary suture. Secondary operations became necessary in 3 cases. The average healing time and wound secretion time was less than eight days. In scarlet fever mastoiditis the healing time averaged 19.9 days. Follow-up of 72 patients with 92 ears operated on from five to thirty months after the intervention showed normal hearing in 85 per cent; in 8 of the 10 cases with impaired hearing the loss of hearing was due to long continued processes in the middle ear prior to operation. The plastic result was excellent. The method is recommended in all simple cases of resection of the mastoid process.

Book Notices

Surgery of Modern Warfare. Edited by Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. Sub-Editor for Medicine, C. Allan Birch, M.D., M.R.C.P., D.C.H., Senior Physician, North Middlesex County Hospital, London. Volumes I and II. Third edition. Cloth. Price, \$20. Pp. 506; 507-1108, with 1,128 illustrations. Baltimore: William Wood & Company, 1944.

With the close of the war in Europe it is again possible to assess the lessons learned from a large experience with trauma resulting from combat. The advances of surgery and its related sciences in the past twenty-five years have resulted in a gratifying decrease in mortality and morbidity. Much of this is due to such successful attempts at prophylaxis as exemplified by the practical elimination of tetanus. A more accurate evaluation of shock and the elimination of much serious infection with modern chemotherapy has resulted in great conservation of life and limb. The surgeon with the armed forces is grateful for adequate equipment, blood and its substitutes, sulfonamide drugs, and penicillin in the treatment of war injuries. He appreciates especially the training and experience of modern surgical teaching, which is basically responsible for the improvement in treatment of combat casualties.

The lessons taught to surgeons by their experiences with modern warfare are well described by the author and his collaborators. The organization of this edition is much the same as that of the last. The work is in two volumes and consists of twenty-one sections representing the opinions of various contributors. Characteristically the writing is clear, precise and literate. Instructions are presented in a typically positive manner which can form an accurate guide to treatment.

Volume I contains a brief summary of warfare instruments and their destructive effects. Such bizarre injuries as result from air and water explosions are effectively described. The nature of wounds and types of contamination are scientifically exposed. It is indicative of the rapid advances made that sulfonamide drugs receive much more attention than in the previous edition, but only a few words can be allotted to penicillin, although its importance is recognized. Other sections in the first volume are concerned with shock, burns, anesthesia and the management of various types of wounds. Some deviations from American practices may be pointed out without undue criticism. The petrolatum gauze pressure dressing treatment of wounds is not emphasized; the tannic acid method, interdicted by United States authorities, is cautiously advocated. The value of whole blood and the need for large amounts of plasma in the presence of shock are definitely suggested.

Wound excision and primary closure are not endorsed as enthusiastically as they were in previous publications. Instead accurate débridement and the so-called surgical toilet are preferred. The local use of sulfanilamide is recommended more wholeheartedly than in former discussions. It should be noted that the use of sulfanilamide locally is not a substitute for adequate surgery. This section has become a particularly valuable summary of knowledge gained by wide and long experience.

Volume II contains sections dealing with regional types of wounds and their treatment. In general, measures to be taken and complications and sequelae to be expected are well outlined. The management of thoracic and abdominal wounds, especially the treatment of hemothorax, is adequately delineated. The section on amputations contains many valuable suggestions which will profit the reader. The doctor with the armed forces has learned to be conservative in his early treatment of war wounds and, conversely, to be more radical in the treatment of the aftermaths and sequelae. Skin grafting, reamputation, and radical orthopedic and plastic procedures are now feasible. The peculiar properties of modern warfare have made wounds of the extremities a serious problem. In this respect peripheral nerve injuries have attracted a great deal of attention. The subject is well covered in this book with the exception of causalgia, which is a frequent and disabling complication. This should receive more attention, since there are now logical procedures to alleviate this distressing condition.

The illustrations cannot be passed over lightly. Their accumulation is a credit to the industry of the author. Many of the anatomic drawings are aptly refreshing. The form and organization of the text are such as to make for ready reference.

The Management of Obstetric Difficulties. By Paul Titus, M.D., Obstetrician and Gynecologist to the St. Margaret Memorial Hospital, Pittsburgh, Pa. Third edition. Cloth. Price, \$10. Pp. 1,000, with 434 illustrations. St. Louis: C. V. Mosby Company, 1945.

This edition, which is slightly larger than the previous one, contains a number of additions and changes, particularly in the chapters on sterility, antepartum care and management of pregnancy, labor and the puerperium. The chapters on x-rays, pelvimetry, toxemia, intravenous infusions and blood transfusions have been rewritten, and sections on caudal anesthesia and penicillin have been added. The reviewer still is of the opinion that the section on sterility (almost eighty pages) does not properly belong in a textbook dealing with "obstetric difficulties." In this section figure 46, which illustrates artificial insemination, shows the tip of the syringe at or beyond the internal os. Injection of semen this high up may lead to trouble. Many other illustrations deal with gynecologic subjects not obstetric ones such as condylomas, coagulation of Skene's glands and Bartholin gland abscess and its treatment by coagulation and surgical removal. Likewise the nine pages describing and illustrating cauterization and conization of the cervix are outside the sphere of obstetric difficulties. Figure 386 (p. 856), "Prolapsus uteri," is the same as figure 69 (p. 147). One other criticism is that the bibliography has not been brought down to date. Titus frequently refers to both Williams and De Lee. In most instances the 1930 edition of the Williams textbook is listed, but this may be because the 1930 edition was the last one Williams himself wrote. However, the reference always given for the De Lee quotations is the 1933 one, although two editions have appeared since then. In spite of these minor shortcomings this book should be in the library of every physician who practices obstetrics. It is well written, is beautifully and abundantly illustrated and is based on an extensive experience as an obstetrician and gynecologist, investigator, teacher and secretary of the American Board of Obstetrics and Gynecology. This edition should be even more popular than the previous ones.

A Symposium on Mammary Tumors in Mice. Publication of the American Association for the Advancement of Science No. 22. By Members of the Staff of the National Cancer Institute, National Institute of Health, United States Public Health Service. Edited by Forest Ray Moulton. Cloth. Price, \$4. Pp. 223, with illustrations. Washington, D. C.: The Association, 1945.

The symposium is made up of twelve articles by active workers in the National Cancer Institute. The introduction, general and historical, is by M. B. Shimkin. The cytology and histogenesis of mammary cancer in mice are covered by A. J. Dalton and T. B. Dunn, the vascular supply by G. H. Algere and H. W. Chalkley, the genetics by W. E. Heston, the hormonal relations by B. M. Shimkin, the milk factor by H. B. Andervont, the effect of diet and other agencies by H. P. Morris, the chemistry by J. P. Greenstein and experimental treatment by H. M. Dyer. In the final article M. B. Shimkin summarizes the main outcome of these articles, with discussion of its bearings on cancer of the human breast. Critical analysis cannot be made of each article. The articles describe well the current state of knowledge and understanding of cancer of the breast in mice. The deep complexity of the problems of cancer is brought out impressively by the detailed consideration of a particular cancer in a particular animal. A high standard is set for symposiums on other types of cancer. The book will be of value to investigators as well as to all who wish to keep in touch with the progress of cancer research.

Bibliography of Industrial Hygiene 1900-1943: A Selected List. Compiled by Ellen F. Bellingham, J. J. Bloomfield, Senior Sanitary Engineer, and Waldemar C. Dreesen, Surgeon, United States Public Health Service. From the Industrial Hygiene Division, Bureau of State Services, Federal Security Agency, U. S. Public Health Service, Public Health Bulletin No. 249. Prepared by direction of the Surgeon General. Paper. Price, 20 cents. Pp. 95. Washington, D. C.: Supt. of Doc., Government Printing Office, 1945.

This helpful list of references covers the period 1900-1943. Although not entirely up to date, it does present conveniently the dependable sources of information about all important aspects of industrial health. Collections of textbooks and reference works should be checked against this list as a test of completeness and adequacy.

Medical Care of Merchant Seamen: A Handbook of Ship and Aircraft Sanitation and Emergency Medical Aid. By W. L. Wheeler Jr., M.D., Medical Director, Grace Line, Inc. Fabrlioid. Price, \$2. Pp. 212, with 25 illustrations. New York: Cornell Maritime Press, 1945.

The purpose of this handy little book of pocket size is "to give the officers and men on shipboard a basic knowledge of what they could do for themselves and their fellow seamen where medical care was not available." It does more than this in that there is included much general information, compactly presented. General sanitation, sanitary measures and disinfection are briefly but well covered, and simple means are described to combat existing conditions to be found on board ship. Many blank forms are presented, with careful complete instructions as to their preparation and disposition. A brief but clear description of elementary anatomy is given, easily understood by the layman.

Under the heading Medicine Chest there is a rather full compendium of medicinal substances with instructions for their use, more or less generally including the cause of the disease or condition and the effect of the remedy. Contagious and communicable diseases are described briefly but sufficiently in language which the layman and inexperienced can understand. Injuries and fractures are discussed, but the handling of fractures is too brief and casual. Certain common conditions which may be expected to appear at any time are well covered, with suggested treatment and "what to do." Childbirth at sea, precautions to be taken on tankers, resuscitation and care of survivors are given considerable attention. A whole chapter of twenty-two pages is given to conditions associated with aviation, completely presented in a general narrative and informative manner as to not only the adverse symptoms and psychologic effects but also the physical factors encountered. Quarantine for ships and aircraft is discussed at length, as is also the method of sending proper messages to obtain pratique. There is a description of spaces devoted to the use of the medical service and their arrangement and equipment, all of which is illustrated by drawings and conveys much detail as a guide to construction of such spaces.

Radio messages seeking medical advice by ships at sea are outlined carefully, that proper diagnosis and treatment may be obtained from a distance, especial emphasis being placed on the details of the patient and his illness. A list of marine hospitals and Public Health Service relief stations is given where aid or treatment may be obtained. A glossary of words and terms used in medical practice is appended to the text. There is also a good index. The book is well printed and bound.

A great deal of simple, understandable detail is contained in the text, and one concludes that the author gave a great deal of thought and review in preparation of it. An unusual amount of information is compressed into a small volume. It is a good general brief treatise on medical and surgical subjects. The style is readable. With this book as a guide the layman or inexperienced officer or sailor at sea can afford the sick or injured person fairly satisfactory care and attention. The book is therefore recommended to those going to sea without medical personnel on board.

Camping for Crippled Children. Editor: Harry H. Howett, Director, Social Research, The National Society for Crippled Children and Adults, Incorporated. By Committee on Camping: Ernest B. Marx, chairman, Gertrude Whitehead, Joseph E. Gemblis, and Harry H. Howett, secretary. Cloth. Pp. 120, with illustrations. Elyria, Ohio: National Society for Crippled Children and Adults, Inc., 1945.

Physicians, teachers of crippled children and social service directors who are interested in the problem of the crippled child have long recognized a need for a source book of information dealing with the problem of summer camps for crippled children. In every community which is large enough to have well developed plans of care for crippled children, the importance of summer camps has been recognized and many camps for crippled children have been established throughout America. Some of these camps have been well planned and well equipped with adequately trained personnel and intelligently outlined programs. In some instances, however, the organizations which were attempting to establish these camps have lacked leadership which was prepared by training or experience to develop a program which would offer the maximum in benefits to the children

whom they wished to serve. This book should be of great help to all those who are interested in the welfare of crippled children. The author of the book has had long experience as a director of social research toward more complete solutions of the varied problems faced by clubs, societies and other organized groups whose efforts are dedicated to the care of crippled children and adults. He has been assisted in preparation of the book by specialists who have collaborated by writing chapters dealing with the various phases of the camping problem for crippled children. This book affords an outline which can be followed in either setting up new camps or in improving those which are already in existence.

Hayfever Plants: Their Appearance, Distribution, Time of Flowering, and Their Role in Hayfever, with Special Reference to North America. By Roger P. Wodehouse, Ph.D., Associate Director of Research in Allergy, Lederle Laboratories, Pearl River, N. Y. Volume XV, a New Series of Plant Science Books, edited by Frans Verdoorn. Cloth. Price, \$4.75. Pp. 245, with 73 illustrations. Waltham, Mass.: Chronica Botanica Company; New York: G. E. Stechert & Co., 1945.

The approach is that of a botanist who is well versed in the field, laboratory and clinical aspects of pollen allergy. Dr. Wodehouse has already published a book and several papers on pollen morphology, in which science he has for years been the leading American authority. In the first fifteen pages he attempts to set forth all the essential facts of botany and pollen aerobiology as related to inhalant allergy. A perusal of these pages leaves one with the impression that wartime restrictions on book paper have caused serious contraction of this part of the original manuscript. A large share of the book is devoted to the classification, description, geographic distribution and clinical evaluation of hay fever plants and pollens. Verbal descriptions are supplemented by many original drawings of plants and flowers and of more than fifty highly magnified pollen grains. The last chapter is devoted to a careful condensation of all published pollen surveys by regions and localities. The format is excellent, and the material is well organized throughout and adequately indexed. Among other helpful features is the glossary. The book will be welcomed by all allergists and should be available for reference to every one concerned in any way with the subject of pollen allergy.

The Governing of Men: General Principles and Recommendations Based on Experience at a Japanese Relocation Camp. By Alexander H. Leighton, Lt. Comdr., Medical Corps, U.S.N.R. Published in Cooperation with the American Council, Institute of Pacific Relations, Inc. Cloth. Price, \$3.75. Pp. 404, with illustrations. Princeton, New Jersey: Princeton University Press; London: Oxford University Press, 1945.

The author is a psychiatrist and social scientist who was assigned to the Japanese Relocation Center at Poston, Ariz. He there observed the social and psychologic problems of both the evacuees and the administration. His description of the events that led up to the strike and the dynamic forces involved in the explosion makes fascinating reading. The factual data are followed by a considerable description of the lessons learned from this experiment. The reader can understand the simple conclusions and advice laid down in the second part of the book after he has gone through a period of pessimism at the stupidity demonstrated by the administration in the data of part I. Certainly this book should be studied carefully by persons who are involved in the government of occupied territories. Any one who is concerned with the administration of groups would profit by this work. This applies to medical officers, industrial psychologists and psychiatrists, teachers and every one who takes his responsibility in a democracy seriously.

Industrial Toxicology. By Donald Hunter, M.D., F.R.C.P., Physician to the London Hospital. Being the Croonian Lectures for 1942 of the Royal College of Physicians of London. Cloth. Price, 10s. Pp. 80. New York & London: Oxford University Press, 1944.

These essays are the Croonian Lectures for 1942 and not, as the title suggests, a complete discussion of industrial toxicology. The entire series is an expression of an extensive personal experience and wide reading. The three metals lead, mercury and arsenic are discussed in the first lecture. Other lectures describe important aromatic compounds, chlorinated hydrocarbons and glycols.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FACTORS WHICH PREDISPOSE TO HYPERTENSION

To the Editor:—What investigations can be conducted to diagnose early arterial hypertension? Of what value is the cold pressor test or the apnea test? Are there any physiologic reactions such as thermal instability, a white demographic reaction to light and heavy pressure, a negative or reverse oculocardiac reflex or a negative hippus that are suggestive of vasomotor instability or prehypertension? What hereditary factors predispose to hypertension, and how can these be assessed quantitatively? How can the important environmental tensions within a family containing one or more hypertensives be evaluated? M.D., Ontario.

ANSWER.—Forecasting the inevitable development of hypertensive disease is impossible prior to the appearance of the major phenomenon hypertension. The etiology of hypertensive disease may be divided into three groups: predisposing, provoking and perpetuating influences. The development of any disorder depends on the reaction of a vulnerable individual to provoking influences. It is impossible to anticipate just what protracted vasopressor stimulation an individual will be subjected to in the future. All that can be assessed is the probable relative importance of constitutional vulnerability as contrasted to multiple and variable provoking factors.

Of the several means of assessing the lability of the vasomotor mechanisms, the cold pressor test is probably the most useful of the clinically applicable procedures. The investigations of Hines and others have indicated a significant correlation between exaggerated response to vascular stimulation by cold and the subsequent development of hypertensive disease. However, one should repeat the test several times before drawing final conclusions. The type of response elicited should be consistent in each individual. Isolated observation should never be given much weight in clinical diagnosis. There are several other means of discovering circulatory instability, but they all suffer from one or more serious drawbacks. For example, it is quite possible to demonstrate exaggerated vasoconstriction induced by emotional stimulation. Anger, fear and annoyance all induce vascular hypertonia, which, if protracted, may lead to hypertensive disease. Exaggeration of such reaction is indicative of vasomotor instability. However, it is impossible to standardize emotional stimuli. The cold pressor test, on the other hand, is standardized as to the intensity and duration of stimulation by cold. As far as known there is no significant correlation between thermoinstability and increased vulnerability to hypertension. The typical migraine physique (Stieglitz, E. J.: *The Migraine Physique*, *Am. J. M. Sc.* 189:359 [March] 1935) is characterized by extraordinary thermostability, and yet these patients frequently develop hypertensive disease. Similarly, significant correlation has never been demonstrated between demographic reaction or the oculocardiac reflex and hypertension. It is sometimes useful to test the circulatory response to certain vasopressor stimuli other than cold or emotion, particularly when it is suspected that certain insults may be playing a provocative role in causing early variable hypertension. For example, it is well known that there exists great variation in individual susceptibility to tobacco smoke. Some individuals respond with a decided rise in their blood pressure following smoking, whereas others give little or no reaction.

The relative importance of environmental tensions within a family group cannot be evaluated with any precision. Their importance varies greatly, not only between individuals, but at different times in the same individual because of recent physical and emotional conditioning. For example, a family row occurring during the phase of premenstrual tension and irritability can be more upsetting than a similar row occurring at some other time. Fatigue, personal relationships, the depletions of minor infections, relaxation induced by alcohol, and the like can greatly affect vulnerability to emotional turmoil. Clinical judgment on the part of the physician is requisite for estimating the relative importance of the purely genetic factors of inheritance and the environmental factors associated with living in a tumultuous emotional environment. No tests can replace sound clinical sense or the judgment born of experience in diagnostic evaluation of all sorts.

INTRAVENOUS THERAPY OF BUERGER'S DISEASE

To the Editor:—What is the status of intravenous infusions of hypertonic (5 per cent) solution of sodium chloride in the treatment of thromboangiitis obliterans? Can any harm come from the prolonged use of such a solution in quantities of 300 cc. on alternate days for one to three months? Jacob Greenblatt, M.D., Stamford, Conn.

ANSWER.—Hypertonic solution of sodium chloride for the treatment of thromboangiitis obliterans (Buerger's disease), which involves both arteries and veins, has been used extensively in certain clinics. Koga's suggestion was based on the idea that the viscosity of the blood is increased in this disease and he advocated large doses of isotonic solution of sodium chloride or isotonic solution of three chlorides to lower viscosity. A group of New York observers use various concentrations of sodium chloride and sodium citrate. Some feel that the 5 per cent concentration of sodium chloride may produce localized thrombi in certain individuals and advocate a 3 per cent or even a 2 per cent concentration. The usual plan of administration is to give 300 cc. of 3 to 5 per cent solution of sodium chloride intravenously three times a week for three months and then gradually decrease the frequency of treatment until a total of nine months treatment has been given. In more advanced cases the intensive treatment three times a week is continued.

There is an increase in pulse amplitude immediately after the injection, but this is transient. Some reactions occur, although they may be minimized by careful preparation of solutions, glassware and tubing.

The question immediately arises why such patients, if they really need sodium, could not receive it orally either in solution or in tablets. Drinking a gallon of chilled isotonic solution of three chlorides or the ingestion of ten 1 Gm. keratin coated tablets of sodium chloride may give striking pain relief and improvement in the status of the peripheral vascular system. The type of patient who shows a high red cell count, a high hematocrit and other evidence of chronic plasma loss will undoubtedly benefit from such a procedure. Later on, when other measures, medical and possibly surgical, have been instituted the sodium chloride solution can be dropped and a liberal intake of water continued.

Aside from the irritation of the vein, the inconvenience and expense of the frequent intravenous injection and the possibility of systemic reaction, patients with a diseased cardiovascular apparatus may be overloaded with a hypertonic solution of this volume, since the 5 per cent concentration of sodium chloride has to attract a considerable amount of water from the tissues to become isotonic. Actually it represents roughly 1,500 cc. of isotonic solution of sodium chloride, the 1,200 cc. having to come from the tissues. The patient becomes very thirsty and replaces this with more water. Hypertension and cardiovascular-renal disease definitely contraindicate such treatment. While this temporary increase in blood volume, in oscillations and in blood flow may be of some benefit, the same effect can be more simply accomplished by the oral ingestion of salt solution or by mechanical means which are capable of filling and stretching the venocapillary bed, such as intermittent venous hyperemia.

LUPUS ERYTHEMATOSUS DISSEMINATUS AND PREGNANCY

To the Editor:—A white woman aged 25, a nullipara, developed an erythematous rash of the entire face during her second month of pregnancy. She had a normal delivery and an uneventful postpartum period except for a temperature of 102 F. the second day, with pyuria which cleared up in seventy-two hours on sulfadiazine 15 grains (1 Gm.) every four hours. There was a slight anemia; the white blood cell count was 12,000. The rash, which was considered toxic and expected to disappear after delivery, has persisted. On the twelfth day post partum there was arthralgia of the shoulders, wrists and fingers, an ascending temperature of 100 to 104 F., a sedimentation rate of 100 and a definite leukopenia, 1,500; the differential count was normal. The urine has pus cells and many red blood cells at times but not constantly. The patient was hospitalized seven weeks post partum. Agglutination tests and blood cultures were negative. The patient died eleven days following hospitalization. The diagnosis of lupus erythematosus disseminatus was made on admission. Penicillin and blood transfusions were tried without improvement in the patient's condition. How many cases are there on record of this disease beginning during pregnancy? Considering the fatality in this instance, did pregnancy mask the symptoms or hold the disease dormant until a sudden flare-up seven months after onset? Will the newborn baby be affected with the same or other ailments?

George H. Jantzen, M.D., Queens Village, N. Y.

ANSWER.—Lupus erythematosus disseminatus is a serious disease with a poor prognosis, especially in pregnancy. It is relatively rare and it is quite unusual to have it begin during pregnancy. Cases have been seen in which a severe exacerbation has occurred during pregnancy. The prognosis in regard to the child, in general, is good.

RIGHT AXIS DEVIATION IN ELECTROCARDIOGRAM

To the Editor:—What is the significance of a right axis deviation in the electrocardiogram of a young adult both as to a theoretically disturbed or arrested prenatal cardiac rotation and also as to its clinical evaluation in the presence of precordial pain referred to the left arm and neck on physical exertion? What are the prognosis, the best management and the most recently accepted life expectancy?

M.D., California.

ANSWER.—The term right axis deviation includes two separate phenomena: (1) a shift in the electrical axis to the right as a result of an altered position of the heart; (2) strain on the right side of the heart. Of course the possibility of a mirror image dextrocardia in which the P, QRS and T waves are inverted must be ruled out. Experience, particularly in the armed forces, has shown that right axis shift is quite common in young people and may be severe in degree without evidence of heart disease. Congenital heart disease may lead to a similar finding or to evidences of right heart strain. Rheumatic mitral stenosis is the commonest cause of right heart strain in a young adult. Bronchial asthma or kyphoscoliosis might also cause a right heart strain at this age. A record similar to that seen in right axis shift or in right heart strain may be produced in the limb leads in a healed anterior wall myocardial infarct. While the last mentioned condition could explain the electrocardiogram referred to and the pain, it is unlikely. Noncardiac causes for the pain should be excluded. The prognosis, management and life expectancy do not depend on the presence of right axis shift or right heart strain but on the conditions which cause them.

VOMITING OF PREGNANCY

To the Editor:—A woman aged 29, apparently in good health, became pregnant three years ago and aborted spontaneously at six weeks after pernicious vomiting of two weeks. Two months ago a pregnancy was started and at one month vomiting again started and, in spite of hospitalization and proper management, a therapeutic abortion was done after three weeks of vomiting. The questions now are How soon may she try again? and What can be done in the meantime, besides building up her general health, to decrease chances of a repetition? Would administration of ovogestron or vitamin B₆ as soon as a period is missed and before vomiting starts be of any value? If so, please state dosage.

M.D., Illinois.

ANSWER.—There is no known way of preventing hyperemesis gravidarum before pregnancy occurs except by making certain a woman's physical condition as perfect as it can be and by arousing in her every determination to use her will power to the utmost in an effort to control vomiting. In the case described, hypnosis should be highly successful. Pyridoxine hydrochloride, or vitamin B₆, may perhaps be of some value if administered before pregnancy even though there is no proof of this. This vitamin, as well as other forms of therapy including adrenal cortex, progesterone, sedatives and above all psychotherapy, should be begun a few days after a menstrual period is skipped. The dose of vitamin B₆ is 50 to 100 mg. given intravenously and repeated as necessary. The dose of adrenal cortex extract is 2 cc. given subcutaneously at daily intervals. If thiamine hydrochloride is used, between 50 and 100 mg. should be given daily. If progesterone is used, 5 or 10 mg. should be given intramuscularly daily. It does not matter when a patient like this conceives again. If she is in good physical condition she may try to become pregnant even as early as four months after the abortion.

MANAGEMENT OF COLITIS

To the Editor:—A patient has refractory ulcerative colitis which fails to respond to any and all treatment, including vaccine. He has had a good response in the past to the concentrated serum, but this seems to be no longer available. A number of pharmaceutical supply houses have informed me that they withdrew their serum because of lack of demand. Presumably the advent of the sulfonamides had much to do with this. However, this patient does not tolerate any of the sulfonamides. I understand that tyrothricin has been used empirically in retention enemas. What is the present status of serum? Is it on the market? What is known of the use of tyrothricin? Can anything be suggested that is not contained in the standard textbooks on the disease or in the current literature?

Frederick L. Sperry, M.D., Detroit.

ANSWER.—With the advent of the sulfonamides, the concentrated serum (antibody solution) came to be used less and less because these drugs were found to be of great help in the control of the active symptoms of the patient with ulcerative colitis. Unfortunately, they have not been useful in all cases of this type of colitis, and the serum continued to find its place for those who were sensitive to the sulfonamides. However, since the demand was small, its distribution was discontinued. Unless some more potent method of therapy becomes available, some of the pharmaceutical houses say that they will have it again for distribution after the war. The sulfonamides which have

been of the greatest help in this disease have been azosulfamide, succinylsulfathiazole and sulfathalidine. So far, clearcut evidence has not been presented as to the value of tyrothricin or any of the other antibiotics as therapeutic agents to be given by rectal instillation. Penicillin has been helpful in the control of the acute symptoms of this disease in some cases. Streptomycin is about to receive a trial.

Other measures of therapy are referred to in a monograph by J. Arnold Barger entitled "The Modern Management of Colitis" (Springfield, Ill., Charles C Thomas, 1943).

LOCAL INFECTION AND DRAINAGE OF CUTANEOUS LYMPHATICS

To the Editor:—I removed a lot of seborrheic warts from the back of a man aged 60, using electrodesiccation with local anesthesia. Some of the warts were as big as a nickel; there were about 20 of them; all were located on the upper back, some just above the midline of the back, horizontally. I covered them with a disinfectant lotion and protected against friction. The healing process was normal. Three weeks later the patient's lymph glands in the groin became swollen. He went first to an internist, who referred him to a surgeon. I did not know about this until the surgeon called me after having the patient under his care for two weeks. He stated that the swelling of the inguinal lymph glands was, in his opinion, caused by the removal of the seborrheic warts and by a possible infection therefrom. The warts had healed in the meantime except for a few which showed some little secretion but no pus. Is it possible that the removal of superficial seborrheic warts on the upper part of the back could cause a reaction such as the swelling of the inguinal glands three weeks after the removal of the warts?

Paul C. Rost, M.D., Los Angeles.

ANSWER.—The cutaneous lymphatics of the trunk are divided on each side of the body into two principal regions: a superior region drained by the axillary nodes and an inferior region from which the lymph is poured into the inguinal nodes and which includes the umbilicus. While most anatomists agree that the line of division between these two regions corresponds to an almost horizontal line, sloping somewhat behind and above, which passes anteriorly through the umbilicus and posteriorly through a point placed a little above the disk which separates the second and third lumbar vertebrae, variations in this level as high as the lateral margins of the tenth rib have been reported. The supraumbilical and infraumbilical regions do not communicate except by fine capillaries.

Although the query does not state the exact level on the back of the seborrheic warts, the fact that a little secretion was present at one of the operative sites might indicate a persistent low grade infection. In the absence of all other causes of inguinal adenitis it is possible that an inflammation of the superficial inguinal lymph glands could result from an infection in the subcutaneous tissue of the back below the level mentioned.

IMMUNIZATION OF INFANT TO YELLOW FEVER AND DIPHTHERIA

To the Editor:—An 8 month old baby is joining his father in a yellow fever zone. Is immunization advisable? Is there any risk of hepatitis due to the immunization? What is the dosage? How soon after passive immunization against diphtheria should active immunization be performed?

Captain, M. C., A. U. S.

ANSWER.—Immunization of a young child against yellow fever is advisable if it is going to a definite yellow fever area. There is no risk of hepatitis from this vaccination, as the vaccine now manufactured no longer contains the human serum which formerly sometimes caused jaundice. The dosage is the same as for adults. Active immunization against diphtheria may be performed when at least fifteen days have elapsed after passive immunization.

LICHEN PLANUS AND GOUT

To the Editor:—Has any one ever described a connection between lichen planus and gout? In one of my cases an attack of gout causes the skin condition to disappear. Whether it is the gout that is responsible for this or the colchicine he is taking is something that would be interesting to know.

Charles A. Beck, M.D., Chicago.

ANSWER.—A review of a considerable literature of recent and past years has failed to reveal any relationship between lichen planus and gout or any cases in which the two conditions were coincidentally associated. It would be of interest if the correspondent or other physicians would note the effect, if any, of colchicine on lichen planus not obviously associated with gout.

PSYCHOLOGIC ASPECTS OF CONVALESCENCE: XX

MAJOR KEEVE BRODMAN

MEDICAL CORPS, ARMY OF THE UNITED STATES (INACTIVE)

BELA MITTELMANN, M.D.

AND

HAROLD G. WOLFF, M.D.

NEW YORK

Sick and wounded soldiers in this war are in many ways more fortunate than those in the last war. They are being treated with benefit of advances in chemotherapy and in medical and surgical procedures; they are being transported with a minimum of trauma, and rapidly, to hospitals and units where they receive definitive treatment. Moreover, they find in their medical officer a physician who has a broader understanding of the psychologic aspects of disease.

The duration and course of convalescence are deeply influenced by the psychologic reactions of the patient. Their importance cannot be overemphasized. The recognition and management of personality disturbances plays as great a part in treatment as does the use of specific medical and surgical procedures. Employment of adequate measures for combating resentments, dissatisfactions, anxieties and fears will minimize symptoms during convalescence, shorten its duration and increase the proportion of completely rehabilitated patients.

I. THE PROBLEM

The incidence of personality disturbances in the armed forces is related to such factors as dislocation as regards family, friends, work, and life plans; regimentation; anxiety-provoking situations, and changes from ideals inherent in peace to others associated with war and bloodshed.

These factors affect all men. The possibility is constantly present that personality disturbances will be precipitated or that minimal disturbances will become aggravated. This danger is especially great during any bodily disorder. These personality disturbances then interfere seriously with recovery and return to duty.

Recent studies have shown that all males of military age can be graded according to their neurotic potentiality and military adequacy.¹ About 80 per cent, barring a 'Tobruk,' a 'Guadalcanal' or a serious infec-

tion of trauma, have no major difficulty. The next 10 to 15 per cent, who have a greater neurotic potentiality, will, with a little luck and minimal aid, successfully adjust themselves. This group contains many persons of high military usefulness. It is doubtful whether it is profitable for the military services to expend time and energy on the worst 5 per cent, who in all probability are unsuitable for military life.

The problem of the medical officer is, then, to concentrate on the remaining 95 per cent, to mitigate the deleterious effects of military experience, hospitalization and illness.²

Perhaps the most important group of all to the physicians in the armed forces is composed of those individuals whose illness from infection or trauma and whose convalescence are complicated and distorted by personality problems. Although all freely admit that such complicated clinical situations exist, the magnitude of the problem is not generally appreciated. Some patients shuttle back and forth between the neuropsychiatry section and the medical or surgical service without either department evaluating both aspects of the disease. Some, because a structural defect is present which could possibly be held to account for the patient's complaints, remain in the medical and surgical wards for undue periods with no investigation of the personality factors.

To define and permit a better approach to this problem, a survey was made of the incidence of personality and psychosomatic disturbances in patients in medical and surgical pavilions of military hospitals.³ Four hundred and fifty unselected admissions to such wards were studied. A psychiatric interview covering significant aspects of the personality and service experience of the individuals was carried out in each case and the percentage of those with 'mild,' 'moderately severe' and 'severe' neuroses determined.⁴ A relatively small group was found to have severe neuroses and a larger number to have mild personality disturbances. The term 'severe' is used to indicate a disorder which will seriously impair the capacity to resume military duties, while 'mild' indicates that personality problems will delay the return to full duty.

These personality disturbances were unrecognized by the medical officers in charge as factors which complicated the patient's response to infection and trauma, which retarded convalescence, and which were likely to lead to decreased military efficiency.

Prepared at the request of and presented under the auspices of the Committee on Convalescence and Rehabilitation of the Division of Medical Sciences of the National Research Council.

The specific studies mentioned in this report are derived from the New York Hospital and the Departments of Medicine (Neurology) and Psychiatry, Cornell University Medical College, New York, under a contract with the Committee on Medical Research of the Office of Scientific Research and Development.

4. For security reasons these figures may not be quoted.

A. *Definition of 'Psychoneurosis.'*—A person designated as 'psychoneurotic' is an individual who has an exaggeration of the feelings and bodily reactions found to some degree in every one. Thus, when some average individuals stand up to address a group they have a momentary feeling of insecurity and tachycardia; when facing a critical mission some are anxious and have to urinate and sometimes defecate frequently; during a perilous experience many individuals are tense and have periods of dyspnea and apnea; when life is threatened they are fearful, and they may vomit and sweat. Broadly speaking, 'psychoneurotic' patients differ from other persons in that these reactions are more readily precipitated and are more severe, persist longer and interfere with adequate performance. In those with so-called 'psychosomatic' disorders the bodily components of these general reactions dominate. The emotional accompaniments may not be easily discerned. In some instances the circulatory, glandular and smooth muscle reactions are so severe as to damage tissue and endanger life.

It is uncommon in the armed forces to find a soldier or sailor whose moods or attitudes alone bring him to the attention of the physician. The patient seldom complains of his anxiety, depression or resentment but commonly of his disorders of bodily function, chiefly substernal pain, anorexia, vomiting, stomachache, backache, headache or pains in the feet. For this reason the officer caring for medical and surgical patients, and not the psychiatrist, sees him first.

Even if the individual is aware of his emotion, he may not relate it to his bodily symptoms. He may feel angry but may not connect that feeling with the pounding of his heart or the burning in his stomach, or the lonely and overdependent individual may feel homesick but may not connect his feelings of bodily fatigue with his depression, or his loss of appetite with his feelings of loneliness and worthlessness.

Certain individuals can stand great hardships of one kind but may break under others. Thus, a man may stand military discipline well, may participate in engagements effectively but may 'break down' when he hears that his mother has died or that his wife has left him. Such a 'break' is most likely to occur if the man has felt that his mother, or his wife, was his only emotional support, the only one who really cared for him.

Personality and psychosomatic disturbances occur in individuals undergoing stress. Anxious individuals 'break' or become at least temporarily inadequate for the military situation more easily than others during physical stress. The inability to rest and to get adequate sleep, together with monotonous food or hunger, contributes to the 'break.' Likewise, infection and trauma weaken resistance. Some individuals of the strongest fiber have 'broken' under such conditions as existed on Guadalcanal: continuous threat to life, limited food, impossibility of resting or sleeping, having to engage in battle while ill with malaria, being bombarded while in the hospital.⁵

B. *The Role of the Nonspecialized Medical Officer.*—Attached medical personnel are in a better position to learn the psychologic aspects of the soldier's or sailor's complaints than are the officers in hospitals. The medical officer attached to troops lives with them. He is aware of the specific problems and difficulties in the 'outfit,' and he knows when rumors or 'high feelings'

are causing upsets. These are reflected in the number and nature of his morning sick calls. He learns which men break down easily, who are chronic complainers, who have anxieties. He is in close touch with the line officers and can get information from them and give advice about the probability of 'breakdown' among the physically and emotionally vulnerable. He can evaluate a complaint in the light of the past history and service performance. He knows all these things before the patient begins to tell his story; the hospital specialist must discover them by questioning. The general medical officer sees him only after incapacitation, while the psychiatrist usually sees him when his breakdown is severe. The attached medical officer is thus the one who sees the patient when therapy can be most effective.

The average medical and surgical officer, even when he has had no special training in psychiatry, should be fully capable of doing this essential work. Continued observation, practice and occasional reading can give him understanding and skill. He does not have to be thoroughly conversant with the theories of psychodynamics any more than a surgeon or a physician has to have at his finger tips the latest facts and theories of physiology. Military physicians have an unparalleled opportunity to become acquainted with basic principles of the recognition and management of personality and psychosomatic disorders and to develop a skill that will make them of great value to the armed services and to the patients they will treat after returning to civilian practice.

Failure to recognize personality factors in disease results in needless and extensive investigation and hospitalization which not only put a strain on the medical corps and its facilities but also intensify and fix a neurosis.

The degree of psychologic disturbance precipitated by hospitalization or prolonged illness may be of such severity that it plays a major role in the course of an illness. A long convalescence increases anxiety and diminishes self confidence and desire to return to duty. Data to support the view that the patient's attitude is an important factor in determining the length of convalescence have been assembled by Powers⁶ in a recent summary of his experience with surgical patients. In an experimental group of 136 as compared with a control group of 98 he found that patients who had had major abdominal operative procedures and who were allowed to become ambulatory one to three days after operation were able to return to work in approximately one-half the time required by those patients who were kept in bed the conventional number of days after operation. Postoperative complications were minimal and about the same in the two groups. Outstanding is the fact that the convalescent period was cut down by approximately one half.

Rusk⁷ has demonstrated in a group of 645 patients from the Army Air Forces suffering from atypical pneumonia that an organized physical reconditioning and educational program shortened convalescence from an average of forty-five days with 30 per cent recurrences to thirty-one days with 3 per cent recurrences. A more recent study in the same branch of the services of patients with atypical pneumonia already on such an

accelerated program has been made by Karpovitch.⁸ It was shown that when they were allowed to engage in 'stepping up exercises' within forty-eight hours of becoming afebrile, instead of after six days or more, the patients were able to leave the hospital in about one week less than the twenty-three days of the average hospital stay. It would seem probable that a major factor in this time saving is a difference in the attitude engendered in the patient by an awareness that his doctor looks on him as well enough to be out of bed and exercising.

Also the experience gained from patients with head injury has indicated that many of the symptoms of the post-traumatic syndrome are related to the anxiety engendered during prolonged bed rest.⁹ It has become common practice to urge the patient to get out of bed as soon as possible, or as early as he desires, the inference being 'that not the least important point of the treatment is that the seriousness of the injury is minimized not only by the statements of the physician but by the permission for early activity.'

The problem of the duration of convalescence with patients in military hospitals is more difficult than with those in civilian hospitals. For a civilian, hospitalization usually means expense and no income; a serviceman has no such incentives to shorten his hospital stay. Remaining in the hospital means relative ease and protection to the soldier or sailor, while return to duty means hardship and danger. Therefore, unless vigorous measures are taken to counteract what is akin to a compensation neurosis, hospitalization is often unnecessarily prolonged.

Our prime purpose in this communication is to present ways and means of dealing with manifestations of personality disturbances that occur in association with infection, trauma and other bodily disorders. When recognized early, these are amenable to treatment and, indeed, to such treatment as can be given by the nonspecialized medical officer. In the following section methods of therapy are discussed.

C. The Ward Round as Group Therapy.—The ward round may be one of the most important prophylactic and therapeutic devices. It is a procedure that is a constructive influence on all patients, whether they are relatively healthy or seriously sick. It incorporates the elements of individual therapy as well as those special features which result from sharing experience with others, acting in a group.

The ward round is a poor time to discuss highly personal problems with patients, yet occasionally patients may be greatly aided when such problems are deftly and objectively dealt with in acceptable language. A patient may be desensitized or deconditioned by frank, open discussion and become aware that his problems are like those of his fellows. The medical officer may single out a cooperative patient and address advice to him which is meant indirectly for the whole group. Never should a patient be scolded or humiliated before the group.

On rounds the patient can be questioned not only about his complaints but also more thoroughly about any improvement he has made. It is easy to let the others know that a patient is better. Improvement may

then become a community affair that reflects credit to the entire ward. The spirit of the group may become so infectious that even the most persistent complainer is caught by it. The bed patients become eager to get up and the ambulatory patients learn to look on discharge to duty as akin to promotion.

If the patients are in one large ward, the medical officer has the opportunity after rounds of talking to the group. He can make announcements of new hospital orders that affect patients, praise or criticize the work of ambulatory patients or read new assignment lists.

Such group instruction includes measures that medical officers routinely institute in the wards without thinking of them as 'psychotherapy.' The patient is made to feel that he is being given individualized and competent medical attention, that he is improving and that he will soon be well enough to return to duty or work. The patient is taught that he is useful and is given the incentive to regain his health. Hospitalization is allowed to symbolize neither pleasant freedom from the rigors of duty nor, on the other hand, a painful or disagreeable experience. The patient is not allowed to think of himself as inadequate or a failure.

All patients should be assigned to a duty in the ward as quickly as possible. This may vary from light assignments such as distributing thermometers to more strenuous work such as sweeping or carrying trays. These duties help the patient to regain confidence in his ability to perform work and emphasize the fact that he is an important and useful member of a community. Patients may be given daily group exercises in accordance with their physical status. The ward master can be placed in charge. Such calisthenics may take the place of the more strenuous games of the well soldier or sailor.

Two features should be stressed in the ward round. The first has to do with the patient's stay in bed. This is not to be considered as a harmless or neutral state. As has already been mentioned, unessential bed rest is a menace. It is well to become suspicious of each day in bed after the temperature is normal. Rules for making the patients ambulatory cannot as yet be laid down, but every day in bed should be a challenge to the physician. Secondly, because every patient must maintain the continuity of his life as a soldier or sailor by learning a new technic or developing an old one, it is during the ward round that the officer in charge can look for progress or work accomplished. The ward officer should make inquiry, examine, advise and encourage as to work done, topics covered and advances made. Such an attitude and behavior on the part of the physician emphasizes that the latter looks on illness as an interruption in the work of a man and not as an end state.

The attitude of the nurses and corpsmen toward the patient is almost as important as that of the ward officer. These assistants should be trained to be understanding and patient with the sick. This, of course, does not mean that a patient is to be allowed to overstep discipline. In fact, it is important that the patient always realize that he is subject to a modified military discipline. Otherwise, during a long hospitalization he may forget that he is a soldier and the return to the rigid discipline of military duty will come as a disagreeable shock.

The good effects of group therapy on the ward round will be enhanced if the medical officer is able to identify

those men who have moderate or serious personality and psychosomatic disturbances which are complicating convalescence from infection or trauma and to give them special attention. An awareness of the large number of these patients and the varied responsibilities of the busy ward physician led to an attempt to devise an 'index' or indicator to point them out. This instrument has been called the Cornell Service Index.¹⁰ It is a paper and pencil procedure, is quick and reliable, is self administered, can be given individually or to groups of any size, can be completed in ten minutes and can be scored within one minute by a nurse or attendant. The 'index' identifies 92 per cent of the patients with severe personality problems and 13 per cent of the mild disorders. One per cent of ostensibly healthy persons will get an abnormal test score. After men who are most seriously in need of help have been recognized, individualized therapeutic measures may be instituted.

II. THE INDIVIDUALIZED MANAGEMENT OF PERSONALITY DIFFICULTIES

To facilitate the identification of those who are most in need of psychiatric appraisal and care, it is recommended that the Cornell Service Index be given to all patients who are capable of completing the procedure. The physician with limited time may concentrate his energies on those patients with scores indicating pathologic reactions.

Patients having symptoms of personality disturbances complicating their illness may be helped by five types of therapy: psychocatharsis, reassurance, explanation, rearrangement of the environment, and regimen. Although these five aspects of therapy will be described in sequence, as though one were to follow the other, no such order is indicated in actual practice. Indeed, reassurance can be given by the physician's first greeting to the patient if he is made to feel that he is an individual rather than a military number. Usually the physician during an interview gains information, allows catharsis, educates by interpreting the data to the patient, and thus reassures him that he is in contact with a sympathetic physician who has the patient's welfare in mind and who will do his utmost to better the situation. Further, the physician will outline a regimen for the patient's recovery, pushing him no more than he can tolerate, but yet with firmness pressing him to his capacity. All of these five steps may occur in one interview in quick succession and in any order.

A. Psychocatharsis.—By this term is meant that the patient is given an opportunity to 'talk it out,' describing his experiences and expressing his fears, resentments, frustrations and anxieties. The physician, in these circumstances, does little but lend an encouraging ear, interfering only occasionally. He may direct the flow or slow and divert it if his intuition tells him that the patient may suffer from the effect of too much self-condemnatory subject matter. Such catharsis is best carried on during the daytime. If it must be practiced at night the physician should from the start give a constructive turn to the discussion. Otherwise the patient may lose sleep and have increased tension and depression on the following day.

To induce catharsis, should it not occur spontaneously, the planned interview is valuable. It is convenient but not essential that this be based on the data assembled on the completed Cornell Service Index which has been given previously to all the patients in the ward. This procedure enables the physician to get necessary information and helps direct the interview constructively. Above all, the physician should aim to learn the attitude of the patient toward his significant answers on the 'index.' To do this the physician must listen attentively when the patient begins to talk about matters of personal importance. Such an interview may be based on the following questions:

1. What are the patient's complaints as indicated by his answers on the 'index' or in his initial conversation?
2. How long has he had them?
3. Has he had similar complaints or other complaints ever before in his life?
4. Under what circumstances did the complaints begin?
5. Is the patient anxious, worried, dissatisfied, angry, lonely? Does he mix well with other people or does he keep to himself? What does he dream about? Does he have nightmares?
6. What is the patient's family situation? Does he have financial problems? Does he feel homesick? Is he worried about wife, children, parents or siblings? Did any of them die? Are any of them sick? How did he react to their sickness or death?
7. Did he have a safe and good home as a child or did either of his parents die? Were they sick and nervous? Did the father drink? Did the home break up? Was he sent to an orphanage or a foster home?
8. Has he had sexual anxieties? What are the facts of his sexual experience and his attitude toward that experience?

The physician should observe the subject carefully during the interview and note whether he becomes anxious or angry, whether he becomes worried, whether his face flushes or turns pale, or whether his breathing becomes difficult. Such changes suggest that significant topics are being touched on. If the patient becomes disturbed, if his answers become evasive or if he says "Why do you ask me this? These are private and personal matters" the physician may explain what these topics have to do with the illness and assure him that the interview will be considered confidential. This may 'clear the atmosphere,' and the patient may be able to continue. If the topics are still too disturbing, it is best to let the issue slide. If one pushes too hard, the interview may have an untoward effect and instead of helping the patient may make him worse.

The physician must control his own emotional reactions and be careful not to reveal any impatience, disgust, anxiety or disapproval which he may feel.

B. Reassurance and Suggestion.—By this term is meant that the physician attempts to persuade the patient by presenting as many facts as possible, that the situation is not as ominous as it appears, that the patient is getting better, that the situation is well in hand and being well managed and that the outlook is good. Furthermore, through his manner and words the physician should suggest constructive or useful ideas and give the patient some conception of himself and his problems that will enable him to 'feel better' about his situation.

The patient is reassured by an opportunity to talk about himself to a sympathetic, understanding individual in a position of authority. This reinforces his self confidence, relieves him of his feelings of helplessness and makes him feel that he has received new strength. It is to be emphasized that the physician's

10. Weider, A.; Brodman, K.; Mittelmann, B.; Wechsler, D., and Wolff, H. G.: The Cornell Service Index: A Method for Quickly Assessing Personality and Psychosomatic Disturbances in Men in the Armed Forces, War Med. 7: 209 (April) 1945.

willingness to assume responsibility and to make decisions and his ability to radiate emotional support give his words a powerful, constructive force. Inversely, the physician's anxiety, procrastination and unwillingness to assume responsibility have an undesirable suggestive effect and undermine the patient's security. (See cases 5 and 6 under III B.)

C. Explanation and Interpretation.—By this is meant that the physician on the basis of his knowledge of the patient specifically, and of mankind in general, attempts to tell the patient in acceptable and understandable language what the situation is and what can be hoped for. He may give the patient an explanation of his symptoms and describe in simple terms the dynamics of bodily changes associated with fear, resentment, anxiety, frustration and dissatisfaction and so dispel misconceptions, ignorance, rumors, fears and discouragement. It is for this reason that a clear prognosis should be formulated promptly, stating what the worst to be expected is and what the best, and the proper steps involved in achieving a desirable outcome. Operative procedures should be preceded by a frank discussion with the patient concerning when he may expect to be out of bed. Besides interpreting symptoms the doctor may instruct the patient on the facts of mental life and attitudes. This aspect of the relationship can be given individually but may often be managed successfully in groups.

The doctor must never give the impression that he believes the patient's complaints are 'imaginary.' He must appreciate that the headache or the stomach discomfort is 'real' and then explain that these complaints do not start in the head or in the stomach but are closely related to the patient's experience in military service and to his attitudes in the existing situation. Finally, he must make it clear that the fears and dissatisfaction and loneliness are not caused by the headache or stomach trouble.

D. Rearrangement of the Environment.—By this is meant that the medical officer shows an awareness of the patient's problems and temperament and a desire to fit the individual into the situation in the military services for which he is best suited. It must be emphasized that an individual with rigid, fixed, uncompromising attitudes can never be properly placed and that the patient must understand his responsibilities when attempts are made to find a job for him. It should also be explained that no attempt will be made to ease his stay in the services. A rearrangement may lead him to a post which in the eyes of many is 'tougher' than his former one but only to give him work better suited to his needs.

On the other hand, it often becomes the medical officer's duty to explain to a disgruntled, resentful, misfitted soldier or sailor that his being in a job in which he cannot use his special training is due to a plethora of such specialists or to some uncontrollable military exigency rather than to indifference on the part of the service.

E. Regimen.—An ordered or organized program for convalescence is an age old and invariably useful therapeutic device. There is no instance in the history of therapy where a physician can be so wrong in one sense and yet so right in another bigger sense. The rationale of baths, physical therapy, occupational therapy, exercises, sports, competitive games and diets cannot be reduced to simple physical and physiologic terms alone. Feelings of security are engendered in patients by pro-

gressive procedures toward the goal of full recovery, provided each one is able to feel that the regimen has been carefully worked out and is being closely supervised.

Sports and games do improve circulation, but they also enhance skill and strength and induce 'fitness,' develop anew the feeling of being part of a team, arouse competitive interest, increase self confidence and aid in relaxation. Occupational therapy affords distraction, supplies variety to the day's activities and gives satisfaction when the assigned task is completed successfully. Physical therapy aids in relaxation and supports the conviction of being cared for.

Regimens of equal therapeutic value, if each has the enthusiasm of the directing physician, can result from diametrically opposed concepts of therapy. Thus, the patient may attribute his recovery to this or that diet, to 'electrical waves' or to specific arm or leg exercises, even though it might more properly be attributed to his improvement in morale. Such false attribution is of no major significance. It therefore becomes of utmost importance that the medical officer organize the step by step progression in the management of convalescence, using his imagination and whatever equipment is available as a means of engaging the individual in the process of resuming his life in the armed forces. A well planned regimen should also include arrangements for recreation.

The regimen should never be punitive. The routine should not purposefully be made disagreeable with the aim of making the patient return to duty in preference to remaining in the hospital.

III. VARIETIES OF PERSONALITY DISTURBANCES OCCURRING IN PATIENTS IN MEDICAL AND SURGICAL WARDS OF MILITARY HOSPITALS

In the aforementioned survey³ of the incidence of personality disturbances among 450 unselected admissions to medical, surgical and orthopedic wards of military hospitals, these disorders were classified as follows: (A) preexisting personality disturbances aggravated by infection or trauma; (B) personality disturbances precipitated by or first becoming evident in association with infection or trauma; (C) personality disturbances in patients with serious defects in structure or function; (D) personality disturbances in patients without gross defects but with excessive complaints and disturbance of function; (E) trauma resulting from personality disturbances. These disturbances were unrecognized as factors complicating infection and trauma. The case histories which follow illustrate the types of problems and in some instances the operation of simple therapeutic measures.

A. Preexisting Personality Disturbances Aggravated by Infection or Trauma:

CASE 1.—A man with headaches following pneumonia feared that he had the same trouble as his invalid father.

A seaman aged 23 contracted pneumonia. He complained of headache, pain in the chest and cough. His temperature became normal in four days. His cough disappeared, as did his difficulties in breathing and the pain in his chest. His headaches, however, continued, and he experienced nausea and vomiting occasionally. Ten days after the onset of his illness, his lungs were completely 'clear' both on physical and on x-ray examination. Nevertheless the headache and the stomach complaints persisted. Neurologic electroencephalographic and spinal fluid examinations contributed nothing.

The headaches and the stomach complaints were severe and incapacitating and prevented his return to active duty. Further,

the patient worried about them and was becoming more and more anxious.

The following information was obtained from the patient in an interview. An abbreviated excerpt follows:

Physician: What is your complaint?

Patient: I have headaches. It gets me in this part of the head. It spreads all over.

Physician: How bad are your headaches?

Patient: They are pretty bad. When I get them I can't do any reading. My stomach is upset. I don't know what I get them from. (The patient's face showed anxiety.) I hope nothing is wrong with my brain.

Physician: Are you worried about these symptoms?

Patient: Well, yes. They just keep coming since I had the pneumonia. I don't know what is wrong with me.

Physician: Have you ever had them before in your life?

Patient: Yes, I had a little after my head was hurt three years ago. (The patient relates that he received a blow on the head by being thrown against the windshield of an automobile. It was not a severe blow. He was dazed and felt nauseated. Within the week after the accident his symptoms were gone except for slight headache.)

Physician: How are your parents?

Patient: My mother is well, but my father is sick. He can get about, but he had an accident fifteen years ago on the railroad. He hurt his head badly and was in the hospital. Since then he has been nervous. He gets bad headaches, and he can't eat the right food, and he vomits. I used to see him suffer; it upsets me quite a bit.

What had these facts to do with the present illness? The patient had been performing satisfactorily during his ten months of service. He liked his unit. When he became sick he had to leave his ship, and he was lonely without his comrades. He was eager to get out of the hospital as quickly as possible so as to be able to rejoin his ship before it left port.

It is to be noted that his first headache was an accompaniment of fever. However, during this depressed state the headache reminded him of his earlier head injury and aroused his old fears that he would have the same ailment his father had for so many years.

It was explained to the patient that his headaches were not due to damage to his brain but that they were connected with his anxieties about his father, himself and his unit. Assurance was given him that if he could dispel these anxieties his headaches would stop. He was also told that he should not brood but should take an active part in useful activity, such as reading about naval problems that interested him and acquiring new manual skills.

In a week the patient's headaches and nausea were gone, and shortly thereafter he returned to duty.

CASE 2.—Pneumonia aggravated nightmares and 'nervousness' in a seaman whose ship had been torpedoed ten months previously.

A seaman aged 26, who had served effectively in the Navy for two years, participated in the campaign in the South Pacific, where his ship was torpedoed. Following this he experienced recurrent nightmares, jumped at sudden noises, had spells of shaking and trembling, was restless and dizzy and perspired excessively. However, he never reported these complaints. While in New York ten months later he developed pneumonia and was admitted to the hospital. The dizziness, light-headedness, trembling and prostration were aggravated and prolonged his convalescence.

B. Personality Disturbances Precipitated by or First Becoming Evident in Association with Infection or Trauma

CASE 1.—A man with nephritis following sore throat had resentment about sulfadiazine therapy and guilt feelings about gonorrhea, which he felt to be causative factors in his kidney disease.

A seaman aged 24, who had been in service for two years and had effectively participated in two major engagements, developed a sore throat. He was treated with sulfadiazine and was freed of his sore throat, but nephritis followed, and he complained of pain all over his body. Moreover, he felt guilty and worthless and was both fearful and resentful for the following reasons: he had contracted gonorrhea a year before the present illness, but despite the fact that he was cured in a short time he feared that his nephritis might be a result of the gonorrhea. He was resentful because he believed that his kidneys had been damaged by the sulfadiazine which

had been given him for his infections. Explanation and reassurance dispelled this man's complaints.

CASE 2.—A man with protracted convalescence following rheumatic fever feared serious complications because he had not been kept in bed long enough.

A private aged 21 with six months of service entered the hospital with complaints of joint pains and fever. A diagnosis of acute nasopharyngitis was made. The symptoms persisted, and acute rheumatic fever was diagnosed on his fourth hospital day. He was transferred to a general medical ward and kept at 'absolute bed rest' for eight weeks. During the last two of these his temperature, pulse rate, electrocardiogram and sedimentation rate returned to normal, and all pains were gone. He was then allowed out of bed, but, instead of continuing to improve, he complained of extreme fatigue, palpitation, dizziness and joint pains. These symptoms increased in severity until by the end of two more weeks he had become unable to get around and had taken to bed. Laboratory and physical examinations showed no evidence of exacerbation of the rheumatic fever. Symptoms were far out of proportion to demonstrable effects of the acute phase of the disease or the inactivity of 'complete bed rest'.

During an interview with the medical officer the patient asked about the rheumatic fever ward. He had heard that there was a special ward in the hospital for patients with acute rheumatic fever. He wanted to know how that ward was different from his, and why he had not been sent there. He asked how serious his disease was, because he had a cousin who became an invalid following rheumatic fever. A specialist had once said that this cousin should have remained in bed for a longer time during the acute attack. The patient expressed considerable anxiety about the seriousness of his own disease and his chances of recovery.

The medical officer assured him that his disease had been mild and left no ill effects. The patient was then transferred to the rheumatic fever ward, where a planned system of work therapy and group psychotherapy was in effect. Within three weeks the patient had been relieved of his anxieties and became completely ambulatory. A short time afterward he was feeling fit and had no complaints.

CASE 3.—Feelings of anxiety, insecurity and failure in an athlete following a broken leg.

A private aged 24, in service for nine months, fractured his right ankle while jumping over a ditch during maneuvers. The injury was a simple fracture of the tibia without complications and mended rapidly. However, he became restless and agitated, slept poorly and lost his appetite. His first attempt to use his leg was awkward and painful, and he said that his fears were confirmed that he would never be able to walk again without pain and a limp. He avoided using his leg, used it poorly when he did, and thus prolonged convalescence. As a child he had been sickly and unable to compete in games. By dint of great perseverance and effort he overcame his 'weakness' and became a successful athlete, frequently winning races. The fracture of his ankle returned this man to the insecure state of his childhood, and he feared that he would again be unable to hold his own or to compete. Repeated reassurance about the good condition of his ankle dispelled his anxiety and encouraged him to walk.

CASE 4.—A sailor who had had three minor traumas of his left leg developed a serious limp following pneumonia.

A sailor aged 21 recovered quickly from pneumonia but his convalescence was prolonged because he limped on his left leg, which he held rigidly extended at the knee. At the onset of the pneumonia he had fainted and had bruised the skin over his left hip in falling. At the end of a week no superficial or deep tenderness remained in the area, and there was no evidence of injury to nerve, muscle or bone to account for the halting gait. A diagnosis of hysterical limp was made.

Six months prior to this illness the sailor during a naval engagement had received a superficial wound in the left calf, so slight as not to require hospitalization. This was followed by a limp. Again, three months later, a heavy swing gun hit him on the left thigh, resulting in a painful contusion which incapacitated him for two weeks. Following his recovery he had a limp

which prevented his climbing ladders, but he remained on duty and his performance was effective.

It was learned that at the age of 16 the patient had been gored by a bull in both thighs and the left groin. He fully recovered from the accident after two months' hospitalization, but he walked with a limp for a short time. The man was given an opportunity to talk freely about his dislike for the Navy, his homesickness, his resentments and anxieties which had become focused in his complaint by the series of minor accidents to his left leg. Within a short time his gait became normal and he was returned to duty.

CASE 5.—Following a minor head injury and exposure to the care of an anxious, oversolicitous physician, an effective sergeant developed a post-traumatic neurosis.

A WAC sergeant aged 24 had been in service for about two years. She had adjusted well, had shown special aptitudes for army work, and had been steadily promoted. While performing her duties she slipped on the ice and struck her head. She was unconscious for a 'few minutes' and was immediately hospitalized. The ward officer kept her 'flat in bed' for ten days. On her way to the latrine on her second day out of bed she felt 'dizzy' and fell. The ward officer exhibited great concern and kept her in bed for a period of another two weeks. After she was again allowed to get out of bed he left strict orders that under no circumstances was she to walk anywhere without a nurse or attendant at her side. This regimen was kept up for the rest of her convalescence in the hospital, a matter of three weeks. During this time she experienced more dizziness and headaches of increased severity. She was given leave to go home but returned to the hospital in a short time, stating that she was afraid of venturing from her bed or room unescorted, because when walking alone she felt extremely dizzy and faint. She could not care for herself. The patient was discharged from the Army with the diagnosis of post-traumatic concussion syndrome.

CASE 6.—An able young officer experienced a minor injury or infection of the shoulder, which because of the undesirable suggestions of the medical officers became the basis of incapacitating hypochondriasis.

A young, high ranking officer had distinguished himself from his student days at West Point. He was highly esteemed by his colleagues and superiors, and his prospects for the future as a soldier were brilliant. He developed shoulder pain while on duty at one of the Pacific outposts. Hospital facilities for complete diagnosis were not available. The medical officers on the island had great concern about the implications of the pain which the officer experienced. They left him with the impression that it might be the result of either a 'severe cardiac condition,' 'severe avitaminosis' or 'some nerve or spinal disease.' He was given many injections of thiamine hydrochloride. The anxiety and uncertainty of the medical officers in relation to the diagnosis and the possible outcome of the disease were transmitted to the patient. He developed severe hypochondriasis, which incapacitated him.

The patient was ordered back to the United States, where a thorough investigation was undertaken. The fact that tests revealed no disease, coupled with the explanation that he had no structural defects, was sufficient to relieve his anxiety, and all hypochondriacal symptoms disappeared. He was able to return to full duty.

C. Personality Disturbances in Patients with Serious Defects in Structure or Function

CASE 1.—A seaman condemned himself for his anxieties and fears following the torpedoing of his ship and lost 30 pounds in weight.

A seaman aged 30 effectively participated in several engagements without injury to his vessel or to himself. In the last engagement his ship was torpedoed and sunk. From that time he had nightmares and trembling. He was restless and anxious, and he complained of dizziness. His symptoms gradually became worse. He lost 30 pounds (13.6 Kg.). He was admitted to the medical ward, where no infection, new growth or endocrine disorder could be found. It became apparent that his loss of weight was the result of his loss of appetite and deficient food intake, associated with anxiety and tension, which the patient

did not wish to acknowledge. He experienced fear in connection with the sinking of his ship. He was a man of excessively high personal standards and considered himself worthless if he sought help for his anxieties and fears. Thus he was in conflict. He was afraid and wanted safety, but he condemned himself for his weakness. He tried to carry on without help, but his symptoms persisted. He felt helpless. After thorough discussion of these factors, his appetite and body weight were restored.

CASE 2.—A conscientious, hard driving engineer was anxious about his family and resentful about his assignment and developed a duodenal ulcer.

A noncommissioned officer aged 35 was admitted to the hospital with pain in the abdomen, which had its onset about two hours after meals. X-ray examination established the diagnosis of duodenal ulcer. The patient had been for many years a conscientious, ambitious, hard driving individual. He aimed to do his job not only well but flawlessly. He worked effectively in the Army as an engineer. He was, however, very much concerned about his family because the members could not live as well after he entered the service as before. He felt that he should have provided better for them. He was also worried about his health. His stomach complaints appeared when, instead of getting a leave as he had expected, he was transferred to an urgent job. He was resentful and disappointed and worried all the more about his family and about his new job. It was in this setting that his complaints began. The management of his illness had of necessity to include consideration of his personality problems.

CASE 3.—A soldier in Officer Candidate School, who felt pushed into assuming responsibilities that he feared and disliked, developed dizziness, headache and arterial hypertension.

A soldier aged 33 had ten months of service and was completing his third week of training in Officer Candidate School. He reported sick with complaints of dizziness, pains and throbbing of the head, continual buzzing in his ears, weakness, tachycardia and palpitation. The complaints had persisted for one month and were increasing in severity. A moderate hypertension was present, varying between 140 and 150 systolic and 90 and 95 diastolic. The patient stated that his blood pressure had always been about 120/80. The rest of his history and physical and laboratory examinations were negative. He was in the hospital for consideration of discharge from the Army. When the patient first reported his complaints and the hypertension was discovered, it was inferred that the symptoms were caused by a rapidly developing hypertension with associated cardiac strain and encephalopathy. Physical examination revealed no cause for a rising blood pressure.

It was noted that the duration of symptoms corresponded approximately with the length of time that the soldier had been in Officer Candidate School. He was therefore asked how he liked the school, what his reactions were toward becoming an officer and about his family, previous profession, schooling and general likes and dislikes. He said that he disliked Officer Candidate School intensely, that it made him 'nervous' and that he constantly worried about assignments and examinations until he developed insomnia. He was afraid to assume the responsibilities of an officer and had applied for Officer Candidate School against his own wishes and only because his commanding officer had insisted that he was good officer material. 'I was afraid to tell any one that I wanted to quit school.' He had graduated from college and for many years was the assistant buyer in a firm owned by a relative. He was single, an only child and had always lived at home with a strong willed and efficient mother, who completely controlled the home. 'She was a very sensible woman and she's always given me good advice.' He liked to be with people who were firm. 'I don't have to worry about what to do.' He disliked to assume responsibility. 'I'm very conscientious and I worry about whether I know enough to do a good job.'

This soldier had an excessively dependent personality, and attending Officer Candidate School and the thought of being a leader of men in a position of responsibility created considerable anxiety. Inquiry made it obvious that his personality was an important factor in the production of his symptoms. The suggestion was made that he resign from school and return to his

outfit, where rapid advancement to his previous grade of sergeant was almost assured. After a few days he accepted the suggestion and resigned from Officer Candidate School. He was seen several times in the next few months. Back again in his old post his symptoms disappeared and his blood pressure became stabilized at the previous level of 120/80 to 130/85. He became cheerful and his anxieties lessened. He said 'Going to Officer Candidate School was just like a bad dream.'

D. Personality Disturbances Without Gross Defects But With Excessive Complaints and Disturbance of Function

CASE 1.—A timid man, overdependent on his mother, had burning in his stomach, aggravated by his military experience.

A private complained of gas, pain and burning in the stomach after eating. He had been in the Army for three months, and during this time these complaints were persistent and had become incapacitating. He said that he had to be on a special diet consisting only of milk, white bread and vegetables. He was frightened on the rifle range, had fallen out of marches five times and developed panic at hearing noises when he had to stand guard at night. On physical examination no structural defect was found. It was revealed that he had complaints of a similar kind for at least six months before entering the Army. He had always been overdependent on his mother, had 'never been away from home' and never ate in a restaurant because it 'made him sick.' At the end of three months this man had still not adjusted himself to military life. The prognosis as regards usefulness in the Army appeared poor, and no therapeutic efforts on the part of the medical officer would be likely to result in a return to duty.

CASE 2.—An ambitious noncommissioned officer developed pain in the legs when faced with competition and possible demotion.

A soldier aged 28, with twenty-two months of service, had spent most of the last six of these as a patient in the hospital. He first entered the hospital with complaints of a few weeks duration of swelling of the lower extremities and pain in the legs on standing and walking. He had never had these complaints before; during sixteen months in the Army he had reported only two or three times for sick call. The pains incapacitated him so that he could only hobble about. He never took an unnecessary step and while in the hospital refused all passes to visit the post exchange, his friends or town. In the short periods when he was returned for trial of duty his officers reported that he would do what he was told without complaint but with such obvious difficulty that he was relieved of duty. He impressed his officers and the medical officers alike as being willing and eager to work yet physically incapacitated. During his hospitalizations he was subjected to thorough examination and laboratory investigations, but nothing was found to explain his complaints. The edema of which he had complained was never observed by any medical officer. The long period of hospitalization finally caused him to become dejected and dispirited. He expressed unhappiness over the fact that he could no longer work and that he was a burden to the Army instead of a help.

The soldier had been drafted in one of the first contingents of troops and because he showed some ability to drill recruits he had been put in a permanent cadre in a training camp. He was promoted until he became a platoon sergeant and would have gone higher except for his lack of education and inability to do paper work. Shortly before his hospitalization new men had been attached to his company, some of whom showed greater ability than did the patient. His commanding officer told the medical officer that 'This man is good but some of the men we now have are better.' His company commander let him know that he would probably be replaced by one of these men. At that point the patient had first reported for sick call with complaints of pains and swelling that prevented his performing his duties. He said that he had always been ambitious but that the lack of education had kept him from realizing his ambitions, that he derived great personal satisfaction from being a non-commissioned officer while men with more education were only privates, and that the threat of reduction in grade made him feel a failure. He said that it would have been extremely painful for him to write home to his wife that another man had proved better than he was. He admitted that his reduction in

rank occurred while he was a patient in the hospital and not while on duty, because he was able to say that it was done because he was sick. His wife was a college graduate and had for many years run and owned a successful beauty shop from which she earned much more money than the patient.

After this interview steps were taken to get the soldier to assume a healthier attitude toward his demotion. Also arrangements were made for transferring him to a new outfit then being formed, in which he had a chance for promotion. He was encouraged to go back to duty; an interview was arranged with his new commanding officer, who told him that if he worked hard he would be promoted. It was explained that he might have trouble with his feet for a while but that the condition would gradually get better; he was complimented on his upstanding character and military bearing and in other ways urged to think of himself as a success rather than as a failure. After this therapy by encouragement, suggestion and adjustment of the environment, the soldier was discharged back to duty. He was seen occasionally during the next four months, during which time he regained self confidence and was promoted to corporal. After the first few weeks his complaints of pain and swelling of the feet ceased and he was able to perform all his duties. He talked with enthusiasm of his new unit and the chance of being promoted to sergeant.

E. Trauma Resulting from Personality Disturbances

CASE 1.—A man who walked in his sleep fell out of his bunk and broke his leg.

A private aged 21 had since puberty been sleep walking about once every two weeks. One night about two months after joining the Army, during somnambulism, he walked out of the upper bunk he was occupying and fell, fracturing his femur. This was the first serious injury he had sustained while sleep walking. On previous occasions while sleeping on a cot or lower bunk he had received contusions and abrasions.

IV. PREVENTIVE MEASURES

As indicated in the foregoing case notes, convalescence may be significantly shortened by simple procedures if the existing disturbance is not too severe or long standing. Moreover, by attention to the attitudes and feelings of healthy trainees, Cohen¹¹ has been able to reduce materially the incidence of hospital visits and to increase the effectiveness of a carefully controlled group of soldiers. Two companies were chosen at random, both filled at the same time and composed of men of approximately the same age and social and economic experience. The experimental group was exposed to four talks on consecutive days of their basic training, which covered (1) natural civilian resentments of army life, (2) regimentation, (3) fear and (4) a summary of all adjustment factors.

Beginning on the first day on which these companies filled and on which the talk began, a record was kept of all sick calls and hospitalization until both companies completed their basic training. The following was noted: There were approximately three times as many sick calls for psychosomatic symptoms in the control group, and between ten and eighteen times as many hospitalization days for psychosomatic symptoms in the control group, as in the experimental group. Also time lost by AWOLs in the control group was twenty times greater than in the experimental group. Finally, performance grades of the experimental group were slightly higher than of the control group.

Another example of what may be achieved by the simplest procedures aimed at the problem of adjustment in the armed forces is as follows: In the station hospital of one of the training camps there were several

11. Cohen, R. R.: Mental Hygiene for the Trainee, *Am. J. Psychiat.* 100: 62, 1943; Factors in Adjustment to Army Life: A Plan for Preventive Psychiatry by Mass Psychotherapy, *War Med.* 5: 83 (Feb.) 1944.

general medical wards and no general medical clinic for ambulatory patients. It was found that many patients in these wards had complaints based on poor adjustment to military life with resultant fears, anxieties, resentments and frustrations. There was instituted a general medical clinic to screen out other such patients before admission to the hospital. At first the medical officers working in the clinic objected to it on the grounds that the patients were not like those who had previously been admitted to the general medical wards; they were not 'medical' but should have been sent to the 'NP' clinic instead. Within six months, however, the number of general medical wards had been greatly reduced. During this time the Army personnel at this camp had not been decreased in number, nor had the special medical wards or the 'NP' wards increased in number or size. This was accomplished because the officers working in the clinic were able to give prompt attention to complaints and provide reassurance and instruction, and because they realized that often individuals with personalities with high neurotic potentiality deteriorated while in the hospital. Furthermore, they appreciated that their own hospital patient load decreased if they were able to keep more soldiers on duty.

In the outpatient clinic of the same hospital, special attention was given to the individuals with complaints referable to the heart but without evidence of structural defects of the heart. All patients found on examination to be in this group were given group psychotherapy by the cardiologist. The number of return visits was reduced to about half within two months of the time of establishment of this psychotherapeutic clinic.

The value of information in preparing men for adverse circumstances is shown by what can be accomplished in filariasis and malaria. As indicated by Rome and Fogel,¹² filariasis is dreaded by troops in tropical climates because they have ample opportunity to see bizarre end results which involve the sexual organs, because it is generally known that there is as yet no satisfactory therapy, and because symptoms and signs of infection are often delayed and insidious in onset. Therefore, infection with filariasis in almost all patients is complicated by fear of sterility, disfigurement of their reproductive organs and of impairment of sexual function. Impotence, so common in anxious persons, therefore, frequently results.

Group instruction in simple terms, concerning the pathology of this disease, supplemented by illustrations and diagrams, can do much to allay fears of disfigurement, impotence, sterility or genital transmission. Instruction on the relation of impotence to anxiety obviates many false conclusions.

Apprehensions about malaria also exist and can be satisfactorily managed by group instruction as to what the disease will and will not do.

V. REHABILITATION

Soldiers who are about to be discharged with a Certificate of Disability have their eagerness to return to their families overlaid with a hesitancy in leaving the Army and a sense of personal failure and inadequacy. This is especially noticeable in those individuals with disability acquired in line of duty. The optimum time for restoring to these men their self-respect and self confidence is during this last period

of army hospitalization. The family's interest and understanding in such a program is of prime importance. Any effort in this direction is sure to pay dividends by enabling soldiers to become productive citizens rather than dependent pensioners of the Veterans Administration.

INTRACTABLE AMEBIC COLITIS

WITH SPECIAL REFERENCE TO THE ULCERO-NECROTIC FORM

DANIEL N. SILVERMAN, M.D.

AND

ALAN LESLIE, M.D.

NEW ORLEANS

Amebiasis is far more prevalent in the United States than is generally appreciated. Although areas of hyperendemicity, such as are present in the Orient and tropics, are not found in this country, the states bordering the Gulf of Mexico may be generally considered as comprising an endemic area, and sporadic cases have been observed over the entire country. In New Orleans alone it has been estimated that the protozoon is harbored by close to 15 per cent of the general population. Most of these cases are symptomatically below the clinical threshold.

Amebic colitis exists as a pathologic entity without the classic picture of dysentery in a high percentage of the cases. Liver abscess, percentage wise, is relatively rare. The symptomatology varies from mild, rare, abdominal discomfort and constipation to acute abdominal pain of the most extreme degree and uncontrollable diarrhea; the duration may range from a few days to many years. The disease often simulates other abdominal conditions so closely that patients undergo laparotomy for such presumptive diagnoses as chronic cholecystitis, appendicitis, pancreatitis and intestinal obstruction. There is great variability in response to therapy. Whereas a long standing case may respond rapidly, a case of relatively short duration may prove resistant. These intractable cases may present vicissitudes of activity for great lengths of time. For example, we have seen cases of uncomplicated amebic colitis with histories of thirty years' duration. There may be great clinical improvement following therapy, with disappearance of amebas from the stools for a short period of time. Apparent improvement in the condition of the bowel is visualized by proctoscopy. The history frequently obtained is one of symptomatic remission for days, weeks or months following exhibition of one of the so-called amebicides. Then follows relapse, which persists until chemotherapy is reinstituted. Recurrent attacks may be relieved by repeated courses of the same drug. Some cases show no improvement whatever after trials of all the known antiamoebic drugs, but this is unusual. The pathologic picture varies from patient to patient and may vary in the same patient at different times from a few widely separated, slightly undermined ulcers to a sloughing, necrotizing, serpiginous generalized ulceration of the entire colon. Furthermore, granulomatous tumors of amebic origin may be encountered anywhere in the large intestine.¹ The factors underlying the change from one state to another in a single individual have not been determined but may

be various. It is apparent that amebic colitis is a disease of protean nature, which may present either classic dysentery or vague symptoms, barely suggestive. As Faust² pointed out, cases with acute fulminating symptoms commonly occur in outlanders becoming infected in hyperendemic areas, where among the natives the incidence of infection is high and the incidence of clinical symptoms low. Cases of chronic nature, on the other hand, may be seen anywhere, as are cases manifesting acute exacerbation of the chronic state. The latter type may follow superinfection with a more virulent strain of ameba or with a strain of the dysentery bacillus. This may have been the circumstance in 2 of the cases being presented here.

REPORT OF CASES

CASE 1.—*Acute fulminating amebic colitis, ulceronecrotic form.*

History.—N. H. T., a white man aged 32, a salesman, was perfectly well until two weeks before admission to the hospital, when while at a hotel in Mississippi he developed abdominal cramps and diarrhea. He became progressively weaker, losing weight, passing fresh blood in his stools and having continuous fever up to 105 F.

Examination.—The patient was acutely ill, dehydrated and emaciated. There was diffuse abdominal tenderness, most pronounced in the left lower quadrant. The pulse rate was 100, the blood pressure 110 systolic and 76 diastolic. Proctoscopy revealed a diffusely necrotic, sloughing and ulcerated mucous membrane.

Urinalysis showed a trace of sugar on one examination. The erythrocyte count dropped from 4,300,000 to 2,200,000 per cubic millimeter, hemoglobin from 75 to 70 per cent. The leukocyte count was 8,750 per cubic millimeter on admission and 7,500 per cubic millimeter several days later, with a normal differential count. No malarial parasites were seen. The blood Wassermann test was negative. Agglutinations for typhoid, paratyphoid and dysentery organisms were negative. Scrapings obtained proctoscopically from the bowel wall were negative for amebas.

Course.—Six days after admission the patient passed a large tissue slough by rectum, reported as "necrotic tissue; normal histology destroyed; most probably sloughed mucosa with large amount of mucus."

The patient's temperature ranged up to 101.6 F., pulse to 120, and respirations between 30 and 35 per minute. Despite infusions and transfusions the downhill course was rapid, and the patient died ten days after admission.

Autopsy.—Gas, fluid and feces were found free in the peritoneal cavity. There were many small and large intestinal adhesions. There was a perforation of the cecum. An 18 cm. section of the posterior wall of the transverse colon was completely missing, presumably sloughed out, being replaced by loops of small bowel. The anatomic diagnosis was rupture of the ascending colon in the region of the cecum; complete sloughing of the wall of the transverse colon; intense ulceration of the whole colon suggestive of bacillary dysentery; acute inflammatory hepatitis; general peritonitis; acute toxic splenitis; acute toxic nephritis. Microscopic sections revealed the presence of amebas in all the layers throughout the entire colon. Culture from the bowel revealed the presence of a gram negative rod, which was agglutinated by known Flexner serum in dilutions up to 1:320.

CASE 2.—*Acute exacerbation of chronic amebic colitis, ulceronecrotic form.*

History.—R. D., a white woman aged 55 whose appendix had been removed twelve years before, had generalized abdominal pain and diarrhea with fever to 101.6 F. for about one year. The symptoms became aggravated one week before hospital admission.

Examination.—The patient was moderately obese, acutely ill, with diffuse abdominal tenderness. Proctoscopy revealed a necrotic, sloughing and ulcerated mucous membrane.

Hemoglobin was 62 per cent (9.7 Gm.). There were 4,000,000 erythrocytes per cubic millimeter. The leukocyte count was 8,750 per cubic millimeter, with normal differentiation. Agglutinations for typhoid, paratyphoid and dysentery organisms were negative. Serum proteins were 4.63 Gm. per hundred cubic centimeters. Chest x-ray and gastrointestinal x-ray studies showed no abnormality. Culture of bowel scrapings revealed the presence of *Bacterium dysenteriae* (Duval). Direct examination of the scrapings showed no amebas.

Course.—Despite infusions and transfusions, the patient became progressively worse and died six days after admission to the hospital.

Autopsy.—There was pronounced edema and reddening of the mucosa of the lower half of the ileum. The distal foot of the ileum showed occasional shallow ulceration. The ileocecal valve was almost completely occluded by much induration and fibrosis in a submucosal pathologic process, which extended from the large bowel side. The wall of the colon was decidedly thickened and, except for an occasional patch of red edematous mucosa, had been completely undermined by what grossly appeared to be a submucosal acute and chronic cellulitis that had been existing for a long time. The mucosal surface was lost only in the lowermost portion of the bowel (approximately the distal 6 inches), where the ulceration presented no typical gross character. The transverse and sigmoid mesocolon and the pericolic fat were thick, indurated and fibrosed.

Several microscopic sections through the gastrointestinal tract, particularly the colon, showed many large areas of necrosis of the mucosa with ulceration, the necrosis being of an undermining nature and tunneling under the mucosa for long distances. In the mucosa and submucosa—predominantly, but found in the muscularis as well as in the subserosa, there were innumerable trophozoite forms of *Ameba histolytica*. Some of these amebas showed ingested red blood cells. The inflammatory reaction present was mostly of subacute and chronic nature, there being considerable thickening of the intestinal wall. In this area some of the amebas were noted within the lumens of the small lymphatics and vascular spaces. Some of these vessels were thrombosed.

Heart blood culture gave no growth in ninety-six hours. Culture from the bowel wall yielded no pathogens. Direct scrapings showed no amebas or fungi.

CASE 3.—*Ulceronecrotic amebic colitis.*

History.—L. M. W., a white man aged 68, under radiotherapy for carcinoma of the bladder, was admitted to the hospital with a history of bloody diarrhea two months previously, at which time proctoscopy showed a condition described as "colitis or proctitis." During the three days preceding admission there were frequent soft black stools, nausea, weakness and one episode of vomiting.

Examination.—Aside from the appearance of chronic and acute illness, this was not remarkable.

Urinalysis was negative except for a trace of sugar and a few pus cells. There were 3,490,000 erythrocytes per cubic millimeter, with 60 per cent hemoglobin. There were 6,900 leukocytes per cubic millimeter, with normal differentiation.

Course.—The patient's temperature ranged up to 102.4 F. There were many soft stools containing blood. The course was progressively downhill, and death took place seven days after admission.

Autopsy.—The colon was adherent to the surrounding structures. There were many areas of necrosis but no area of complete perforation. The mucosa was destroyed by ulceration which involved the entire bowel including the cecum and the rectum. Microscopic examination showed degeneration of the mucosa with extension of the process to the submucosa, with edema and lymphoid and plasma cell infiltration and areas of necrosis in the submucosa. Many amebas were seen in the necrotic zones. The bladder showed a few areas of degenerating

2. Faust, E. C.: Some Modern Concepts of Amebiasis, Tr. & Stud., Coll. Physicians, Philadelphia 11: 101-113 (Dec.) 1943.

neoplastic cells, and the prostate showed a gland cell type of carcinoma (Broders' classification 2). Mucosal scrapings of the colon revealed the presence of motile amebas.

COMMENT

In 1937 Niño³ reported a case of "ulceronecrotic intestinal amebiasis with amebic tumor of the cecum and ascending colon" which prior to pathologic examination was thought to be tuberculosis. Death with peritonitis followed resection of the ascending colon. A second small mass was noted at the splenic flexure. It is felt that although the term "ulceronecrotic" has excellent descriptive qualities, it should preferably be reserved for the pathologic picture as seen in the 3 cases presented in this paper. In Niño's case and in other cases of similar nature amebas have been demonstrated in the granulation tissue comprising the granuloma and in the necrotic areas of amebic ulcerations. In cases 1 and 2 the trophozoites of *Endameba histolytica* were demonstrated in all layers of the colon, from mucosa to serosa. Figures 1 and 2 are sections made through two widely separated areas of the colon in case 2. Figure 3 is a high power magnification of an area of deep amebic penetration visible in figure 2. In the

other two developed deep ulcerations of the colon, which perforated. Death ensued in one case in forty-eight hours, in the other in about five days.

Similar observations were apparently not infrequent in the early days of American occupation of the Philippines and in Panama before 1915.

Cases 1 and 2 were complicated by the presence of dysentery organisms, Flexner in one case and Duval

Fig. 2.—Section through colon showing partial destruction of the mucous membrane and penetration of amebas into submucosa and muscularis, with associated inflammatory reaction.

in the other. It is possible, although not necessarily probable, that this combination of pathologic processes results in the diffuse ulcerating and necrotizing process which in one case caused a major slough of the transverse colon and in the other a large mucosal slough of the rectosigmoid. Faust² mentioned combined amebic and *Shigella* colitis without emphasizing any particular pathogenic summation.

Case 3 did not present the striking findings of cases 1 and 2, but the fact that the entire colonic mucosa was

Fig. 1.—Deep ulceration of colon, showing amebas in the crater and in the necrotic granulation tissue forming the base of the crater; complete destruction of mucous membrane.

third case there was demonstrable extension to the submucosa. There was nothing remarkable in the nature of the pathologic change, which after all was classic for the disease. The unusual feature, however, was the involvement of the entire colon in an ulceronecrotic process. In the past this extensive process has rarely been observed in this country. According to the following memorandum from Dr. E. C. Faust⁴ it has occurred in hyperendemic areas, such as China and the Philippines:

Three cases of fulminating dysentery, admitted to the medical wards of the Peking Union Medical Hospital, Peking, China, in October 1922, were of special interest because of the prostration of the patients on admission. Two were native policemen and one a shopkeeper. All were given a presumptive diagnosis of bacillary dysentery, but laboratory examination of the freshly passed stools proved them to have amebiasis and to be negative for *Shigella* organisms. Following specific diagnosis all of the patients were placed on yatren (i. e. chiniofon), which had been discovered in 1921 and was being given clinical trial. One of the patients responded well and was soon convalescing. The

Fig. 3.—High power magnification of an area of figure 2 showing presence of many trophozoites of *Endameba histolytica*.

destroyed by the ulcerative process warrants its inclusion here.

Although cases of this type have been uncommon heretofore in the United States, an increase in incidence may be foreseen for two reasons:

1. The local dissemination of the disease.
2. The importation of virulent strains of amebas from the oriental and tropical war theaters.

3. Niño, F. L.: *Amebiasis intestinal ulceronecrotica y tumor amebiano del ciego y colon ascendente*. Novena reunion Soc. argent. de pat. reg. 2: 813-843, 1937.

4. Faust, E. C.: Personal communication to the authors

SUMMARY

In 3 cases of ulceronecrotic amebic colitis the unusual feature common to all of them was the extensive nature of the pathologic process, heretofore a rare finding in the United States, but apparently more common in hyperendemic areas, such as China and the Philippines.

ABSTRACT OF DISCUSSION

DR. WALTER L. PALMER, Chicago: The first essential in the diagnosis of amebiasis is to think of it and to look for the ameba. Amebiasis is present in all sections of the country. Drs. Silverman and Leslie report an incidence of 15 per cent in New Orleans. In various studies we have made in Chicago the incidence has been lower, from 2 to 4 to 6 per cent of carriers, and I think that figure compares quite well with most figures in Northern cities. After the epidemic of 1933 and 1934 in Chicago the incidence of amebiasis dropped rapidly and quickly returned to the level which had existed prior to the epidemic. Most severe cases of amebic colitis respond to emetine and chiniofon or vioform. The most essential point in the treatment of the chronic cases is the continuance of treatment. Often a patient is treated for a few weeks with temporary recovery and then the treatment is dropped and in the course of a few months the disease recurs. Not only do we have mixed infections with the dysentery organisms but also, occasionally, hemolytic cocci. Gonzalez and Vejar of Mexico City have recently reported a case of fulminating amebic dysentery, complicated by staphylococcal hepatitis, treated with penicillin with dramatic recovery. There are occasionally cases in which one finds amebas and sees a typical proctoscopic picture of non-specific ulcerative colitis in which the diarrhea and the proctoscopic findings persist after intensive amebicidal therapy and when amebas cannot be demonstrated, even on repeated examination, in the stool. None of our cases of this type have come to autopsy. The relationship between the two conditions is debatable. The same situation arises with regard to bacillary dysentery. There are many who think that all cases of non-specific ulcerative colitis are in fact instances of chronic bacillary dysentery in which the organism is, for some reason, not demonstrable.

DR. M. G. SPIESMAN, Chicago: I want to contribute briefly 2 cases of amebic granulomas of the rectum which were mistaken for carcinoma. A doctor aged 55 had frequency of stool and bleeding from the rectum. A diagnosis of carcinoma was made by a protologist, and he was advised to have the rectum resected. He was referred to me. I did a routine biopsy and a direct smear. The biopsy showed only inflammatory tissue, and the direct smear microscopically revealed amebic trophozoites. The diagnosis of amebic granuloma was made and we fortunately were able to cure this man's "carcinoma" with antiamebic treatment. Another case was sent to me with the tentative diagnosis of carcinoma of the rectum. A colostomy had already been performed. A routine biopsy showed inflammatory tissue, and a microscopic examination from a direct smear revealed amebic trophozoites. This man also was relieved of his suspected carcinoma with antiamebic treatment. These 2 cases emphasize that in every case of suspected carcinoma one must rule out amebic infection.

DR. DANIEL N. SILVERMAN, New Orleans: I have a different opinion as to the cause of chronic ulcerative colitis. After studying more than a thousand cases of acute and chronic bacillary dysentery over a period of years I believe that neither *Bacterium dysenteriae* nor *Endameba histolytica* has anything to do with the cause of chronic ulcerative colitis. Only in comparatively few instances, such as this, have we had sufficient thickening and narrowing of the bowel to give a similar radiologic picture. On the other hand the cultures have been negative in practically all of my cases of chronic ulcerative colitis. So I, like others, am on the fence as to the etiology of chronic ulcerative colitis.

THE GENERAL PRACTITIONER AND THE RETURNING VETERAN

COLONEL LAUREN H. SMITH

Neuropsychiatric Consultant, Ninth Service Command,
Fort Douglas, Utah

AND

CAPTAIN HORATIO C. WOOD

Chief, Neuropsychiatric Section, Walla Walla Army Air Field,
Station Hospital, Walla Walla, Wash.

MEDICAL CORPS, ARMY OF THE UNITED STATES

Adequate and specific medical care for the returning veteran is now a need in every American community, especially in smaller or suburban areas. It must be recognized as an increasing problem, for the medical profession will be faced with it more and more in the next few years. Professional interest must be kindled, because the major solution should be inspired and implemented by personal activity of the general physician, not only to provide the best health protection for our soldiers who will be returning to each community with their scars of physical and mental wounds, but also to insure the continuing prestige of the general practitioner. If the members of our recognized medical societies are not ready to carry on with this challenge, they will find themselves shunted to one side by some group who will appear to meet it. As there are psychiatric aspects to be considered, some suggestions which might be helpful in general practice are herewith offered.

The psychiatrist is expected to be more sensitive to and aware of, and perhaps less ill at ease with, the problem of psychiatric returnees. But although they may constitute one of the largest groups in the medical problem, there will be enough neurologic, surgical, orthopedic and other types of cases to discourage any feeling that the whole job should be shrugged off on the doorstep of some ladies' aid committee which may act with professional assistance no greater than lay or nonmedically trained psychologists or social workers. The deciding factor which will may unwittingly jockey the medical group away from meeting the situation and form the wedge of an increasing lay supervision of community health needs can be the inertia of the local general practitioner in taking up the challenge.

In many communities there are groups of earnest, intelligent and well intentioned citizens who are, or will soon be, taking steps to anticipate and prepare ways and means to meet the problem of the returning veterans. In almost every community this will likely result in the formation of a civilian council, which will make use of the professional services of lay workers from the staffs of social and welfare organizations. Perhaps financial aid to furnish salaries for administrative, secretarial and clerical help will be offered, provided by legislation or solicited from state or federal grants. If this comes to pass, as seems indicated by recent events, it is important that it be developed with and by the organized medical group, especially in the average nonmetropolitan community. In order to secure the best results and for the most able administration, the medical problem had best be kept well in the hands of the community's physicians through their group corporate body, the county medical society. And this can emphasize the potentially fine job which can be done by physicians in their own regular practice for the bulk of those veterans needing medical and psychiatric attention. The strain on veterans' facilities plus the

preferences of some veterans to be treated in their own community by physicians of their own selection may make treatment in government hospitals one of choice only for those cases demanding a specialization of treatment, equipment and appliances or a duration of hospitalization incompatible with office or local practice.

Perhaps the greatest deterrent for the average physician in his willing and spontaneous assumption of this work may be an inordinate sense of inadequacy and a resulting hesitancy in approaching the psychiatric problems which will make up a large number of the cases encountered. Before making any definite suggestions as to a general picture of development, certain points concerning the general practitioner's ability in the field of mental and emotional illness should be considered.

The majority of clinical psychiatrists will agree that they feel more kindred to the general practitioner than to any other one group of their medical brethren. The well informed, thinking physician who possesses a broad experience in general practice has found that 60 per cent or more of illness encountered in his office practice is of psychogenic origin without any somatic basis. The problems and procedures of handling these patients are therefore familiar to the general practitioner, and he is well situated to handle adequately the majority of psychiatric problems he may encounter, and for recognizing and directing to the right places those few which will need the attention and care of specialists.

It is interesting to look at the obverse of that coin. The psychiatrist feels more at home with, and sees his professional problems better understood by, the general practitioner than by the surgeon or the otolaryngologist, albeit the understanding perhaps is somewhat naive and more intuitive than conscious. Why, then, is it that the general practitioner often does not feel professionally more at ease with the psychiatrist and the better enabled to tackle such patients? Yet he will do minor and even major surgery without a qualm, attack ophthalmologic conditions and laryngeal or ear problems in his stride, but if almost any chronic and familiar occupant of his waiting room chair is labeled "psychoneurotic" he at once will begin to look a little askance and feel somewhat hesitant or less assured in this person's presence.

The answer is, of course, that most physicians do know their psychiatry and their psychoneurotic patients intuitively rather than in the light of a conscious, disciplined knowledge; and while they work with hands and material technics on surgical patients and see immediate results, with the psychoneurotic they are constrained to work chiefly with intelligence, thoughtful considered planning and personal direction. The results are often so slow in developing and so full of seemingly contradictory changes that the physician may feel he is not quite sure whether it was luck or good management that did the trick.

But every general practitioner in an ordinary non-metropolitan community has as an inherent part of his medical armamentarium the most important requirement, other than skill or technical knowledge, needed in the psychiatric treatment of a patient. This is the simple but detailed and comprehensive knowledge about the patient, his family and background, his environment, his ambitions and hopes and the threats impinging against those. This is the contact which the practitioner in a large city so inexorably loses; that which the psychiatrist with strangers for patients must so painstakingly delve for and evaluate.

Recognizing then these natural assets, this intuitive knowledge of how to handle patients which results from

real experience, they can be developed by some means of orientation which might help in formalizing such knowledge to the end that the physician may acquire more confidence and assurance in its use.

The basic premise on which any successful psychiatric approach must rest is the conviction that people, and particularly the individual at hand, are inherently normal and good, and that any deviation from this in behavior or conscious motives and intent is due to illness—physical or psychologic, which in the great majority of cases can be cured.

The man who is attempting to correct a psychologic illness cannot believe that the sufferer is incurable without thereby losing his chance to effect a cure. He should not invoke the folklore of character defect, heredity, natural perversity or some other such pious self excuse without being ethically bound to turn over the case to some one else. To make these statements is not to put the cart before the horse or to indulge in wishful thinking. It is merely a recognition of the fact that all the witch burning in the whole of the fourteenth and fifteenth centuries never led to the finding of a cure for hysteria, while earnest, sympathetic, intelligent application of medical men as divergent in theory and technic as Pinel, Freud or Austen Riggs has resulted in an ever more favorable prognosis and outcome for the psychoneuroses.

People act the way they do because they believe it is the only way of acting that will assure them happiness. And except in the case of insanity or mental deficiency or organic mental disease all that is needed to bring about psychologic balance and reintegration is to find the reasons for their behavior and intentions and slowly, let it be repeated with emphasis, slowly, to reeducate them—not by sudden or immediate expostulation and haranguing nor by dumping on them our reasons for considering their actions or ideas unwise: reeducation is achieved by little hints here, and demonstrations and little advances there, until they see the light and accept those reasons deeply as their very own, and frequently much of their new learning must come from their impressions stimulated by our own actions and our emotional attitudes toward them rather than by our actual words.

Psychoneurosis is merely emotional illness deriving from ignorance, false experiences or fear, occurring in a person with an essentially normal mind and nervous system but disturbing the integration of psychologic forces that lead to adaptive behavior. It is reasonable to state that there are few if any psychoneurotic persons who cannot be aided in regaining normal mental health by a physician who is friendly, observant, skilful in understanding and influencing, and practical in manipulating the environment as needed.

So called neurotic or normal is merely a matter of position along a scale of security and self confidence, knowledge and belief. Each of us has the potentiality of developing a psychoneurosis if we are only subjected to a sufficiently intense or chronic strain of ignorance, or of false and threatening experiences, or of fear.

Fortunately the great bulk of psychiatric persons who are and will be returning from the armed forces represent this illness of psychoneurosis, and the problem of mental disease, or insanity, is relatively small.

Of a million men or women there are a certain number who break down with real mental disease. The same percentage ratio holds for men in the army, perhaps increased to some extent, but not too significantly.

A large majority of the mental illness breaking out in men of the armed forces is of an acute type which tends to recover rapidly, especially when the patient is returned to civilian life. Such problems are the working area for the specialist in psychiatry.

The present day treatments available for frank mental disease, even of the schizophrenic, the manic depressive or involutional type, and the problems inherent in home care, will warrant committing almost all such cases to institutional treatment.

On the other hand, it will be found that, with a few exceptions, the majority of neurotic patients can be treated successfully by the physician in general practice if he is practical in being sympathetic and understanding, especially if his knowledge of psychiatric concepts is improved and formalized by even a minimum of reading in today's psychiatric literature.

With this in mind, at the end of this article is appended a list of reading that is authoritative and comprehensive, which should be of real practical value in the approach to the understanding and handling of psychoneurotic patients but which is not too technical, and which is not really geared for the specialized handling of the more severe cases.

A few exceptions should be noted in the matter of psychoneurotic conditions that would benefit by specialized attention—the cases of serious, major complicated type or degree, which are as follows:

1. The obsessive-compulsive cases, the serious reactive depressions or other, perhaps severe hysterical cases, which we realize are more than the general physician can hope to cope with. Most of these will be no different than ones of similar type seen before in pre-war civilians.

2. The particular cases of so-called battle psychoneurosis, or operational fatigue—the combat or operationally induced neurotic states—which can so easily and quickly be cured by the specific psychiatric technics developed in this war.

One interesting case account was recently published in *News Week*:

Boredom.—Far from New Guinea, where he killed 50 Japs and was decorated twice, ex-paratrooper of Passaic N. J., was bored. He told police last week it was the awful quiet which made him rob a New Jersey taxi driver, go to New York and then kidnap a lawyer to drive him back to Jersey City.

He may have been suffering from operational fatigue. There are two necessary facts present: 1. He was overseas in combat. 2. His behavior is now abnormal. If it could be ascertained that he showed no criminal tendencies before induction, the diagnosis would almost be made—and if in addition it was found that he suffered from insomnia, nightmares or a nervous stomach or that he was jittery or anxious, he could be sent off to the nearest rehabilitation center, where experience has shown that it is possible to restore his prewar personality or a reasonable facsimile thereof.

A young lieutenant was referred to one of us for evaluation pending a court martial for being drunk and disorderly in a nearby town. The first thing noticeable about him as he entered the office was the flushed, rather expressionless, tired face, with deep forehead furrows and widened palpebral fissures—a facies typical of many of the men who are suffering anxiety and chronic nervous tension. He admitted that he had just had another court martial some few weeks before for being drunk and out of uniform, and that this time he expected to be discharged in disgrace. He had been drinking

pretty heavily ever since he had got back to the States seven months before. But he had not been a heavy or unusual drinker before then. His tour of duty was in the South Pacific area, where he had been a navigator on a heavy bomber and had completed twenty-six missions—or strikes as they are called in that area. On the twenty-fourth mission the plane had been forced to make a water landing, but the crew had all been saved after eighteen hours in their rubber life boats. He went to some trouble to explain that this water landing was not his fault and why it wasn't—offered the statement that no one of the crew except the pilot realized that. This officer had not been sleeping well. He had been having nightmares, particularly of combat scenes. He had noticed that his concentration was failing and his appetite had fallen off, although he had suffered no actual nausea or vomiting. He had startle reactions at loud or sudden noises and was restless most of the time. He had been feeling tense and on edge in planes since getting back, especially when they were taking off or landing. It is obvious why all ideas of court martial were quietly retired and why he was sent to a rehabilitation center for treatment.

A third case, excerpts of which are quoted from a report by Lieut. Col. Roy R. Grinker on a case of depression, with anxiety of one year's duration, shows the amazing results attainable by specialized treatment in these operational fatigue cases, in that it was relieved in one week by pentothal sodium narcosynthesis and brief psychotherapy:

A captain aged 25 presented an expressionless face; his muscles were quite rigid, indicating a great deal of tension. He did not volunteer much information and never smiled, and his speech was retarded. The patient had been a flight leader in a pursuit squadron and had fought successfully until about his twenty-fifth mission, when a friend who had been flying on his wing went up in flames. However, he stated that he continued fighting and successfully completed his tour of duty, although feeling bad and depressed. He returned to the United States, refusing the chance of remaining as commanding officer of a squadron. He had been reassigned to a job in the United States which he liked very much and wanted to keep, but his depression continued and was accompanied by severe startle reactions. When any one came into his room and made a sudden noise or turned on the light he would jump out of bed with great anxiety. In addition to the depression and its concomitants there was considerable insomnia with battle dreams, which repeated some of the very severe traumatic incidents of his combat experiences. However, he maintained fairly good control of himself and continued to fly. He attempted to decrease the anxiety and depression by drinking, but the only result was an increase in anxiety. He stated that he tried hard to forget his experiences but found it impossible.

In his first interview Lieutenant Colonel Grinker submitted the patient to a pentothal abreaction of the episode in which his friend and plane went up in flames. This treatment was followed by a discussion of the episode and reassurance against personal guilt feelings after the patient had become conscious again. Clinical notes indicate his improvement:

The next morning the patient entered the interviewing room and stated "I feel like a load has been lifted from my mind, like a great relief. I slept well last night, awakened once and went right to sleep again. I had no dream. This morning I feel good."

On the third day, "The next day the patient entered the interview smiling and stated frankly 'I must say I haven't felt so good as I feel now for a long time. I slept well and had no dreams.' He felt as if he could carry on."

To make a long story short, by the end of the week the patient felt that the load had been lifted from him completely. He wanted to go back to duty and felt capable of carrying on and in Grinker's opinion had been brought to a satisfactory point at which to terminate treatment.

"Therefore we did not treat him any further but returned him to duty." Six months later, reexamination revealed that he was entirely well and competently performing his flying duties.

The last 2 cases were both from air force casualties. But with a change in the props (a stage setting word, not air force lingo) they might have come from any combat service or area. Muscle tension, fidgetiness and restlessness, startle reactions, insomnia and nightmares, irritability, difficulty in concentrating, physical symptoms of emotional stress—particularly functional stomach trouble—these are the signs that appear.

But not everybody with so-called operational fatigue has just this picture or has been in combat. There is one other type to consider, the soldier who has been sent overseas on duty or to places where he has been exposed to long stretches of unimaginable loneliness or monotony. This has been seen in crew members of bombers who flew only on submarine patrol in the Caribbean, in aviation engineers who had been stationed for months in some inactive, isolated area of the Aleutians, and so many men have returned from Ascension Island with this condition that some psychiatrist dubbed it "Ascension Island neurosis." It lacks the startle reactions and the nightmares of the other type of operational fatigue and has more hypochondriacal and neurasthenic elements to it.

These examples point out certain leads of importance. When confronted with a veteran, find out reasonably soon what he was a veteran of. As soon as he says he was overseas he is a little more suspicious of a specific war-induced neurosis; he is more than suspicious if he was in combat or if he was assigned for any length of time to an exceptionally lonely, inactive place. On the other hand, if he never got close enough to either the Atlantic or the Pacific oceans even to spit out of the United States—if his neurosis was well developed before he was inducted and his behavior has shown no especial difference either before or after, he was sick before he came into the Army and he is still sick. But with this difference: The community will now be judging the medical group on the basis of whether anything is done for this man's illness. And if physicians aren't active in treating him, others will be wanting to try.

Psychiatric professional interest would tend to lead to emphasizing the importance of the mental and emotional medical needs of the soldiers who are and will be returning. Statistics, however, will show that this is not overemphasis. And despite the bulk of the psychiatric cases, numerically there also will be many veterans who will be in need solely of strictly organic medicine.

Many of the persons who will come for treatment will have had hospital records of study, diagnosis and treatment in the Army, and there should be instances in which these records would be of great value to the physician in work with the soldier. An army regulation¹ now authorizes the Veterans Administration to release to physicians a copy of these records provided the request is accompanied by a signed statement of

approval from the patients. It is imperative that this aid be not overlooked.

Not all men returning will be in need of any professional help. We must remember that the majority of men will meet the issues involved in adjusting to new home town conditions in an eager stride. The same common sense, courage, imagination and spirit of growth that enabled each one of them to become a fighting soldier will be used in picking up the life channels they desire at home. For those less fortunate or those needing special help, let it be provided by the man they can trust and depend on—the home town doctor.

It may be stated unequivocally that any intelligent general practitioner who uses general medical common sense, combined with a reasonable degree of acceptance of known established psychiatric principles and orientation, can successfully apply these principles of treatment in the majority of cases.

Finally, one simple suggestion may be considered feasible of development in most communities: A committee should be formed in each county medical society with a title somewhat along the lines of "Committee for Study of Veterans' Health Problems." This committee should be assigned two functions: (1) to collect information, to contact state and federal bureaus, to prepare plans and procedures, and to act as a central bureau for all physicians, and (2) to offer its services as an integral part of the veterans' council of each town, under the supervision and direction of that council's committee on physical and mental health problems, and to act as the physicians' representative on that council in its meetings and discussion of medical matters.

The fundamental contribution will be in the personal practice of each physician. He is not only the unit by which this work may be initiated but also the keystone to maintain it.

Roger Bacon.—Embedded in the superstitions of the thirteenth century, any man who knew gunpowder, handled the furnaces, alembics and other instruments of an alchemical "laboratory," prophesied "horseless carriages" and ships moved without sails or oars could easily stand accused of practicing "black arts" (i. e. magic) and writing heresy punishable by imprisonment. Such was the fate of Roger Bacon, the English born Franciscan of Oxford. Yet his "Opus Majus" ("Great Work"), ordered by and delivered to Pope Clement IV in 1267 but not published for five hundred years, reveals clearly that this learned and traveled friar, pupil of the great Bishop of Lincoln, Robert Grosseteste, dealt with "magic," not to practice but to expose "the mad acts of magicians" by the true test of "experimental science." He was no sorcerer who looked on mathematics as "the alphabet of all philosophy" and studied optics for the "sweetness" and "nobility" of "this very beautiful science."—*The Autobiography of Science*, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

A STUDY OF DIARRHEA OCCURRING AT ARMY AIR FORCE HEADQUARTERS, CALCUTTA, INDIA

CAPTAIN EDGAR A. LAWRENCE

Flight Surgeon

AIR TRANSPORT COMMAND, ARMY OF THE UNITED STATES
AND

CAPTAIN ROBERT E. BENNETT

Flight Surgeon

AIR SERVICE COMMAND, ARMY OF THE UNITED STATES

Outbreaks of diarrhea are not uncommon in army camps in the United States. They are usually of short duration and easily controlled. In India, throughout the entire year cases of diarrhea are seen in all army installations. During the monsoon season they tend to increase in number, become far more severe, are of longer duration and often show a much higher incidence of dysentery. Whereas in the United States outbreaks of diarrhea are ordinarily treated by routine army methods, it cannot be overemphasized that in India and other areas of the Far East every case of diarrhea must not only be looked on with grave suspicion but examined individually with the most minute care. In India, diarrhea occurring during the monsoon season, which in this locality (southern Bengal) lasts approximately from June 20 to September 20, is often referred to as "monsoon" diarrhea; a poor term, since it only tends to obscure the true etiology of the disease.

In this study we shall attempt to show the conditions which brought about a high incidence of amebic and bacillary dysentery during a twenty-three day monsoon period at this air base as well as the measures employed to keep the incidence of these diseases at a minimum.

The air base is situated on the banks of the Hooghly River, approximately 15 miles from the center of Calcutta. It is enclosed on three sides by densely populated and disease ridden Indian villages. Estimates indicate approximately 14,000 persons within an area of a half square mile, most of whom live on or near the waterfront in the immediate environs of the base. The village streets and fields are littered with all kinds of debris. Decaying garbage, human and animal excreta and occasional foul smelling carcasses of dogs and bullocks left lying for days at a time are the usual conditions found. Sanitation in its most elemental stage has made no impression on the populace. Obviously conditions of that kind are extremely conducive to the breeding of flies in and around the base, domestic (*Musca domestica*) and bottle flies (*Chrysomya megacephala*) being the common varieties.

From Jan 1, 1914 to the end of June 1944, 569 soldiers reported at sick call with the complaint of diarrhea. During July there were 205 cases, or approximately double the incidence of any previous month. Such an increase is not to be construed as an epidemic but rather, we believe, a result of the rainy season and natural increase in fly breeding.

During the period from July 11 to August 2 all cases reporting at sick call with the complaint of diarrhea were carefully studied and the following data obtained: (1) history and physical examination relative to the attack of diarrhea; (2) length of tropical service; (3) stool examinations by both fresh saline and iodine preparations and concentration methods where indicated; (4) cultures of fecal specimens obtained by rectal swabs and planted on inhibitive

media, bacteriologically traced as to type specificity of dysentery organisms by the Subcommittee on Dysentery, headed by Dr. Carl Ten Broeck.¹

DISTRIBUTION

During this twenty-three day period, 198 consecutive cases of diarrhea were studied. The causes were as presented in table 1, from which it can be readily seen that 104 cases (52.5 per cent) exhibited either amebic or bacillary dysentery or both. Most forms of non-pathogenic protozoa were seen either alone, together or accompanying one or other forms of dysentery. Stools that were negative or showed nonpathogenic flagellates microscopically were not followed further as to etiology but may well have been due either to simple dietary indiscretion, a change in the types of food ingested in India or one of the *Salmonella* group of organisms, which not uncommonly present dysenteric symptoms often indistinguishable from those of bacillary or amebic dysentery. *Endolimax nana* was seen in heavy numbers in 37 cases not presenting amebic or bacillary dysentery,

TABLE 1.—Distribution of Cases

Parasite or Bacteria	No of Cases	Percentage of Total
<i>Endameba histolytica</i>	31*	15.6
Bacillary dysentery	66	33.3
Both <i>Endameba histolytica</i> and bacillary dysentery	7	3.5
<i>Giardia lamblia</i>	4	2.0
Nonpathogenic protozoa	47	23.7
<i>E. nana</i> , <i>C.</i>	41	20.7
Negative microscopically	41	20.7
Total cases examined	198	

* Two recurrent cases

TABLE 2.—Symptoms and Incidence

Disease	Total Cases	Abdominal Pain	Nausea	Vomiting	Weakness	Tenesmus	Fever
Bacillary dysentery	66	26	29	12	21	10	21
Amebic dysentery	31	1	10	7	10	5	10
Both bacillary and amebic	7	4	5	1	4	2	5
	104	31	44	20	35	17	36

a point of interest in view of the fact that in only 3 cases were they seen in a group of 100 supposedly normal individuals. It would be foolhardy to suggest, but conceivable, that in certain cases in which they are seen in large numbers (occasionally as high as 30 to 40 per high power field) and where no other parasites are found they may possibly be at least a contributing factor to the diarrhea.

SYMPTOMS

The onset of symptoms was sudden in 70 per cent of the bacillary dysentery cases, in 48 per cent of the amebic dysenteries and in 57 per cent of all other cases. The outstanding symptoms and incidence of each are given in table 2.

It may seem that tenesmus was the only outstanding symptom peculiar, but by no means entirely, to bacillary dysentery. Fever occurred approximately in only 50 per cent of the amebic and bacillary cases, and therefore it is important to point out the practice, so often seen in Army medical personnel, of taking temperatures to determine the possibility of dysentery is of very limited value. We were frankly unable to

¹ Subcommittee on Dysentery, Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General

decide from the symptoms what type of disease we were likely to find under the microscope. The only clue to bacillary dysentery, apart from tenesmus, was the frequency of bowel movements, for whereas the average number of stools passed were from 4 to 7 per day in the unclassified diarrheas and a similar number per day in cases of amebiasis, the average in bacillary dysentery was from 8 to 20. In this series nausea was quite an outstanding feature in all types of diarrheas, and vomiting was not unusual. The climate and chloride loss from vomiting and perspiring may well account, apart from the disease itself, for the high incidence of weakness. No frank cases of shock were noted.

LENGTH OF TROPICAL SERVICE

Soldiers arriving overseas during the monsoons were apparently just as prone to intestinal disease as those with long terms of service. There was no evidence to suggest that any resistance or immunity was acquired from prolonged tropical service.

LABORATORY FINDINGS

The routine examination of stools in all cases of diarrhea cannot be overemphasized; as has been shown, in this series neither the symptoms nor the presence of fever gives one a positive clue to diagnosis.

In this study, stools were passed in an adjoining latrine and examined immediately in a warm state. The whole stool was mixed and a fresh saline and a 1 per cent iodine preparation made. In cases of doubt, and in the studies of carriers, a portion of the specimen was concentrated and examined for cysts. The characteristics of the gross stool and microscopic picture conformed to the classic description. In those with bacillary dysentery the stool was of a bloody mucous consistency, devoid of fecal material in 74 per cent. In those presenting amebiasis 32 per cent were of a watery, bloody fecal consistency, 29 per cent were watery and fecal but lacking in gross blood and some showed streaks of mucus and blood surrounding a semi-solid stool. In this series we were unable to demonstrate gross blood in any case that did not prove to be dysenteric. Microscopically the diagnosis of bacillary dysentery was made in the presence of numbers of red and white cells and large macrophages and naturally absence of pathologic protozoa. The diagnosis of giardiasis and amebiasis was made in the presence of the active trophozoitic or encysted forms.

Because of the interest and cooperation of the Subcommittee on Dysentery,¹ rectal swabs were taken and cultured from all cases of diarrhea. Their report will, no doubt, appear later, but it is sufficient to say at present that, although only one culture was obtained during the acute phase of the disease, 25 (37.8 per cent) of the 66 cases of bacillary dysentery were positive for one or the other strains of *Shigella* organisms. No *Shiga* type organisms were isolated.

TREATMENT

All cases of dysentery were immediately isolated and evacuated to a nearby general hospital, where they received recognized routine therapy. It is of note that no deaths were recorded nor were any complications reported.

SOURCE OF INFECTION

The water supply, naturally, came under grave suspicion; however, weekly samples of both drinking and ice water were bacteriologically tested and found to be potable. Water sediments were examined by Major

G. J. Dammin¹ and found to be negative for amebic cysts. Purification of water is accomplished by a process of flocculation and filtration and, finally, chlorination.

Another obvious source of infection for which, at present, there is no remedy, is the local hotels, restaurants, bars and other such establishments. No check is made of the food handlers employed in such places, nor is there adequate fly control. Many of the Army personnel, particularly transients, and those on leave, live at these hotels and consequently are openly exposed.

In an effort to determine the degree of fly hazard, as far as the transmission of dysentery was concerned, 25 of them were caught in various mess halls and cultured on inhibitive mediums. Live bottle and domestic flies were picked up from screens by forceps and allowed to crawl over a small area of the plate. Twenty-two, or 88 per cent, showed cultural and morphologic characteristics of coliform colonies. Owing to lack of facilities, no further bacteriologic study was made to trace further either the group or the genus. The fact, however, that such a high percentage showed gram negative coli group organisms is presumptive evidence of transmission. It was unfortunate also that owing to lack of cultural mediums and a dissecting microscope no study could be made for amebic cysts that might have been present in the contents of the flies' intestines. In view of the surrounding breeding grounds and access to human excrement it is more than possible that these flies harbored encysted forms of *Endameba histolytica*. In further support of such an assumption, the fact that the incidence of amebiasis was reduced by the intensification of fly control measures is, at least, partial proof on deductive grounds.

CARRIER STATE

The extent to which food handlers and other human beings not connected with the serving of food play a major part in the spread of infection, as far as amebiasis is concerned, is a question. As regards bacillary dysentery, though, there is no question that man is a definite reservoir—flies playing purely a passive role in its transmission. It should be stated that all food served at the

TABLE 3—Carriers

Men Examined	Bacillary Dysentery			Amebic Dysentery		
	Number Cultured	Number Positive	Percentage Positive	Number Examined	Number Positive	Percentage Positive
Indian employees	148	5	3.3	289	22	7.61
White soldiers	116	12	10.3	100	3	3.0

base is thoroughly cooked prior to serving, no raw vegetables are prepared, and every precaution is taken to prevent manual handling of food by Indian bearers. Bearers' nails are examined and pared, uniforms are kept clean and adequate facilities for hand washing are provided.

Although the numbers of individuals in table 3 are small they are sufficiently representative of a cross section of the total number of troops at the base. As can be seen in the cases from whom rectal cultures were made, the greater percentage of positives occurred in the Army personnel and not in the native food or water handlers as might be suspected.

The number of contact carriers of amebiasis in 100 unselected cases was surprisingly low in the Army personnel and only somewhat higher in native food handlers.

CONTROL MEASURES AND RESULTS

Flies appeared to be the main vectors in passive transmission. Local British government authorities were notified, and stringent sanitary measures in the surrounding area of the base were carried out. As far as the base itself was concerned, sanitation teams made up of Indians under the supervision of noncommissioned officers were organized. Latrines, buildings, tent areas and all open air breeding places were sprayed with *Dichlorodiphenyl-trichloroethane* (DDT) or some form of pyrethrum spray or aerosol bomb. Greater numbers of fly traps of the box conical type were placed at advantageous intervals around all mess halls and possible breeding places and at garbage collecting stations. Refuse cans were checked for tightly fitting lids. All mess hall doors and windows were repeatedly examined and the screening and woodwork repaired where necessary. The control of flies by these measures was both dramatic and gratifying.

As a means of eradicating, as far as possible, amebic carriers in Indian food handlers and in view of the difficulties of individual therapy, mass treatment was initiated. Each Indian working in or around mess halls received a daily dose of a half grain (0.032 Gm.) of carbarsone for a period of ten days. Repeated stool examinations are being done on all food handlers and a careful stool examination done on all new applicants.

The command and Indian latrines were examined for cleanliness and maintenance was enforced. Notices with regard to hand washing were posted.

Where possible, in the command, all carriers of either amebic or bacillary dysentery were segregated and treated. Facilities, however, were such that not all soldiers could be examined. There is little doubt that our own troops are acting as a reservoir of bacillary and, to a lesser extent, of amebic dysentery.

As a result of these control measures and prompt isolation of dysentery cases there has already been a definite and appreciable drop in the incidence of diarrhea and dysentery. In a three week period from August 2 to August 23 only 92 cases reported at sick call with the complaint of diarrhea and of these there were 21 (22.8 per cent) cases of bacillary dysentery and 11 (11.9 per cent) cases of amebiasis. Though the total cases of diarrhea were lower, there was only a small drop in the numbers of dysentery cases. This drop cannot be explained on the grounds of periodicity in fly breeding, for flies of all types continue to be prevalent in other areas surrounding Calcutta.

CONCLUSIONS AND SUMMARY

1. All cases of diarrhea occurring in the tropics must be approached with grave suspicion and utmost concern. Employment of the routine gross and microscopic stool examination cannot be overemphasized. The fact that so many untreated early cases of amebic and bacillary dysentery tend to become chronic quickly, often leading to lifelong invalidism, should in itself be an indication and reason enough for thorough diagnosis and early institution of adequate therapy.

2. The term "monsoon" diarrhea is misleading and only tends to obscure the true etiology of the disease.

3. The high incidence (52.5 per cent) of amebic and bacillary dysentery is shown in a series of 198 consecutive cases of diarrhea occurring during the monsoon season.

4. The often used Army doctor's method of differential diagnosis between simple diarrhea and dysentery

by checking the temperature and, if normal, administering one of the sulfonamide drugs for a period of twenty-four to forty-eight hours is to be deplored. As has been shown in this series, the temperature in dysentery is often normal and the symptoms are not too far removed from those of unclassified or nonspecific diarrheas. Not only does the use of the sulfonamide drugs for so short a period, when they are effective in controlling the disease to some extent, lull the physician into a sense of false security but they also can be considered no more than palliative if dysentery is actually present.

5. There was a high incidence of bacillary dysentery carriers (10.3 per cent) in our own troops.

6. All known carriers in Army personnel should be promptly treated and segregated.

7. If Indian food handlers, by virtue of military necessity, are employed, repeated stool examinations should be made.

8. In India and throughout the Far East, sanitary discipline and every method at our disposal for the control of flies must be instituted and vigilantly maintained.

MODE OF PRODUCTION OF
PULMONARY EMBOLI

EARLE M. CHAPMAN M.D.

AND

ROBERT R. LINTON, M.D.

BOSTON

Pulmonary embolism secondary to venous thrombosis, especially in the deep veins of the legs, is a disorder that has been feared by physicians for centuries. Since Valsalva's¹ classic experiment in 1740 in which he described the effects on man of holding the breath in inspiration and making an expiratory effort with the glottis closed, there have been numerous studies on venous pressure. However, it was not until the method of Moritz and Tabora² was introduced in 1910 that comparable measurements of the venous pressure were recorded. They and subsequent investigators noted a great increase in venous pressure in subjects performing the Valsalva experiment but on review of this literature we find that their observations have been chiefly on the veins of the arm: the physiologist Méan³ did observe a great increase in the volume of the peripheral veins in both the arms and the legs.

The recent work of Bürger⁴ and of Meyer and Middleton⁵ has emphasized the great danger to persons with heart disease of even a modified Valsalva experience (acts of defecation, parturition, coition, lifting, straining at work or in sports) and they even attributed "bedpan" deaths to heart failure from sudden changes in venous pressure and total hemodynamics. The emphasis of this type of vascular strain has been placed on the heart, but we believe that sudden and often fatal pulmonary embolus is a more common result of such acts of straining by those confined to bed by illness or

operation. Indeed the single case description by Meyer and Middleton is classic for pulmonary infarction, but they failed to mention this possibility. The dramatic plugging of the pulmonary arteries by clots released from the leg veins after straining on a bedpan has been witnessed probably by nurses more often than doctors; in our own hospital this "Haley sign" of pulmonary infarction has been attributed for years to an astute head nurse.

In our determinations of venous pressure in the arm and the leg it will be noted that, like previous observers, we found a rise of several centimeters in the arm vein pressure during the forced expiratory effort with the glottis closed. The difference between this reading and the reading in the leg when recumbent is probably due to the fact that the venous reservoir drained by the superior vena cava is much smaller and more subject to pressure by muscles and other structures. However, when sitting in the bedpan position there is a great rise in normal venous pressure in the legs (hydrostatic effect), but this in turn shows a greater increase on the forced expiratory effort.

Our explanation then for this mode of release of mural thrombi that so often lie in the leg veins is in the observed facts that venous pressure and volume in the leg rise sharply during a Valsalva experiment. Associated with this rise in venous pressure, the return of blood to the heart is temporarily impeded so that the peripheral veins become distended with blood, which may loosen an insecurely attached mural thrombus. With the drop in venous pressure during the next inspiration the dammed venous blood rapidly empties from the peripheral veins, washing with it any loosely

Venous Pressure in Arms and Legs During Valsalva Experiment

These experiments were done with the needle in the antebrachial vein of the right forearm, the sphenous vein of the anterior midleft calf of subject F. M. C. and in the vein on the dorsum of the left foot of R. R. L. All readings are in millimeters of water. Direct saline tube method.

attached thrombus. Although this explanation is simple, we are unable to discover its previous description.

The application of this concept in the care of bed patients is obvious. The patient should avoid forced expiration with the glottis closed, especially in the sitting position in bed. The prevention of fatal pulmonary embolism by femoral vein interruption in cases of thrombosis of the deep leg veins, first advocated by Homans⁶ in 1934, has proved to be a safe operation. In a large series of cases so treated at the Massachusetts General Hospital Allen, Linton and Donaldson⁷ have shown that it is without deleterious effect to the legs and can be done on ill patients with life-saving results.

VENTILATION IN THE SPREAD OF CHICKENPOX AND MEASLES WITHIN SCHOOL ROOMS

MILDRED WEEKS WELLS, M.D.
PHILADELPHIA

School ventilation, which has necessarily been curtailed on account of fuel shortages during the war, will probably never return to prewar standards. Enlightened opinion, which formerly opposed, on hygienic grounds, lowering the volume of air change, now recognizes the potentiality of higher standards of sanitary ventilation through air disinfection, which can practicably provide the hygienic equivalent of ventilation impossible of attainment by actual air replacement.

Studies, begun in the autumn of 1937, were undertaken to test the hypothesis that the spread of air-borne infection in school rooms could be controlled by radiant disinfection of air. If micro-organisms are air borne, it follows that in a group of persons sharing a confined atmosphere for a given period of time the chance that an infective organism floating in the air will be breathed by a person susceptible to that particular disease is proportionate to the concentration of susceptibles in the atmosphere, just as the chance that a susceptible person breathing the air will become infected is proportionate to the concentration of the specific organisms in the air, the latter being an equilibrium between the rate at which they are added and the rate at which they are removed. In atmospheres where occupancy is intermittent and of relatively brief duration, such as school rooms, the rate of removal is primarily a function of ventilation.

Ventilation of occupied spaces is usually expressed as volume of air change (in cubic feet per minute) either per room or per occupant. Sanitary ventilation, on the other hand, has been defined as the number of cubic feet of air per minute per susceptible,¹ sanitary ventilation thus being in terms of a particular disease.

VENTILATION IN CLASSROOMS AND PATTERNS OF SPREAD OF CONTAGIOUS DISEASE

Those familiar with the patterns of spread in day schools of chickenpox and measles are aware that these diseases, introduced into the relatively immune upper classes, seldom do more than smolder along for a generation or two before dying out. In the more susceptible lower grades, explosive outbreaks and dynamic epidemics are apt to occur (though at times an apparently definite exposure of highly susceptible children may, surprisingly, have no sequelae). If these diseases are air borne, as is now rather generally conceded, this is to say our present standards for the ventilation of school rooms, which provide air change on a basis of total pupils regardless of age or susceptibility, are ordinarily sufficient so to dilute the micro-organisms discharged by an exposing case as to prevent dynamic spread with concentrations of susceptibles such as pre-

From the Laboratories for the Study of Air Borne Infection, University of Pennsylvania School of Medicine, Philadelphia. These laboratories are supported by a grant from the Commonwealth Fund to the University of Pennsylvania for studies on the mechanics and control of airborne infection.
Many have aided in these studies, including Prof. E. B. Wilson, who was consulted on the epidemiologic problems; the medical and teaching staffs of the various schools; Mr. Frederic Robinson of the Hanovia Chemical and Manufacturing Company, which lent the equipment for the study in the Germantown Friends School, and Dr. L. J. Buttolph of the General Electric Company, which lent the equipment for the study in the Swarthmore School.

vail in upper classes but are insufficient with concentrations such as are encountered in classes of young children.

There are almost no data reported in the literature as to the critical point of susceptibility above which infection will spread in day schools and below which it will die out, and we have found none at all which are correlated with ventilation. Thomas² studied the spread of measles in infants' departments (children aged 3 to 8 years) in the Woolwich District of London. He concluded that "measles may be expected to appear and spread in a department when the number of children unprotected reaches about 33 per cent, and usually, except when some special conditions obtain, it ceases to spread when the proportion is reduced to 18 per cent." A report from the medical officer of health on the London epidemic of measles in 1929-1930³ indicates that a similar equilibrium existed some quarter of a century later. Measles, it was concluded, tends to assume an epidemic character in individual school classes when the proportion of susceptibles reaches 30 to 40 per cent and to continue to spread until the proportion falls below 15 to 20 per cent.

installations, described in a previous paper,⁴ provides, by central hanging fixtures, irradiation of the upper region of the room above the 7 foot level. The radiation units consist of two crossed "Safe-t-air" tubes in a shallow aluminum pan reflector, made especially for the purpose by the Hanovia Chemical and Manufacturing Company. These fixtures were also hung in other rooms where the children gather as a group. Only where time of exposure seemed negligible, as in halls and lunch room, was it deemed permissible to utilize direct radiation, the most efficient method of radiant disinfection of air.

II. The boroughs of Swarthmore and Nether Providence provide two groups of public schools in adjacent suburban areas, each about 15 miles from Philadelphia. These are public schools, but the areas from which the children come are well to do. The several schools of both groups are built to meet the Pennsylvania code as to space, light and ventilation. Classrooms of 7,000 to 8,000 cubic feet capacity, each planned to accommodate 30 pupils, are provided with mechanical ventilating systems designed to provide 30 cubic feet of fresh outdoor air per pupil per minute.⁵ Since only

THE PHILADELPHIA EXPERIMENTS

The studies, begun in the Germantown Friends School in 1937, were twice expanded and since the autumn of 1941 have consisted of similar experiments in two neighboring private schools in the city of Philadelphia and two groups of public schools in adjacent suburban areas:

I. The Germantown Friends School and the William Penn Charter School are private day schools located a few squares apart in Germantown, a ward of Philadelphia. Only boys are admitted to Penn Charter, and the sisters of many of these boys attend the coeducational Germantown Friends School. The two groups thus mingle in the homes, the boys of the two schools meet for sports, and the religious and social life of the children interlocks without the schools. Both schools are ventilated only by windows. Penn Charter is wholly unirradiated, while in the Germantown Friends School the classrooms and other gathering places of the children of grades 1 to 4 (two sections to each grade) are irradiated. The design of the classroom

exceptionally did classes exceed 30 pupils in size, this ventilation may be considered the minimum. The schools of Nether Providence are wholly unirradiated, while the two elementary schools of Swarthmore (grades kindergarten-6) are irradiated. In Swarthmore each classroom is equipped with four side-wall fixtures, each containing a 30 watt (36 inch) "Germicidal" tube in high transmission glass, made by the General Electric Company. Halls and lunch room, as in the Germantown Friends School, are directly irradiated.⁴

The simple epidemiologic technics which have been used were also described in the previous report:⁴

1. "Susceptibility" to chickenpox and measles indicates that a history of no previous clinical attack was obtained from the child's parents. The disadvantages of this method are recognized, but the high intellectual and economic level of the groups reduce them to a minimum, an assumption supported by the low number of second attacks of these diseases reported. Similar records as to previous attacks of mumps were kept,

The code of school room ventilation was amended recently to permit as much as 50 per cent of the air to be recirculated, but we are told by the architects of these schools that they were built to the former standard and that recirculation would be impossible with the present design.

but the recent demonstration by Enders⁶ of the acquisition of immunity to this disease by subclinical infections does not permit such data to be considered a reliable index of susceptibility.

2. The mother of every child with contagious disease was questioned as to the last day of attendance in school and date of the onset of symptoms. From the length of the interval between it was judged whether or not the child caused an exposure of his classmates to his infection.

3. Cases following a class exposure in the child's classroom by the accepted incubation period were deemed class secondaries unless the child had also been exposed in the home (home exposure being presumably heavier than class exposure).

various susceptibility groups. There are given the total number of exposures and the number which were negative, that is, in which the exposing case did not give rise to any further cases, in which the dynamic chain of infection was broken. Only initial class exposures are included, that is, the first exposure of that class during the school year. If 1 or more cases occurred before the class was exposed (the child being for any reason away from school during his infective period), the susceptibility of the class was recomputed as of the date of the first exposure. This limitation to initial exposures was decided on because reexposures of classes were frequently to multiple cases, which introduced complexities, a negative result following exposures to 2 or more cases deserving more weight

EFFECT OF RADIANT DISINFECTION OF AIR

In testing the spread of chickenpox and measles in classrooms with and without radiant disinfection of air, i. e. where the experiment consisted in varying the concentration of micro-organisms in the air, only classes with a similar concentration of susceptibles are comparable. This has been especially important in these experiments because the irradiated groups became, grade for grade, progressively more susceptible as the experiments continued. We have therefore divided the classes into five groups as to susceptibility, those under 20 per cent susceptible, 20 to 39, 40 to 59, 60 to 79 and 80 to 100 per cent susceptible. In tables 1 and 2 we have recorded the outcome of exposures in irradiated and unirradiated classrooms of the classes falling into these

than a negative result following an exposure to a single case, results being fractional when multiple cases gave rise to fewer secondaries than the exposing cases.

The total number of class exposures and the number which were negative (unproductive) are given separately in the tables for each school. Since in the test schools it is necessary to separate the upper and lower grades (only the latter being irradiated), this has also been done for the schools wholly unirradiated. In summarizing, however, the percentage negative for the unirradiated and irradiated groups as a whole is computed.

(a) *Outcome of Exposures in Unirradiated Classrooms.*—Despite the small number of exposures in each group, the chance that an exposure in an unirradiated classroom will cause other cases increases with increasing susceptibility with a surprising regularity.

6. Enders, J. F.: Observations on Immunity in Mumps, *Ann. Int. Med.* 18: 1015-1019, 1943.

Thus of 13 exposures to chickenpox in unirradiated classrooms where classes were less than 20 per cent susceptible, not a single exposure gave rise to a secondary case. Of the 15 exposures in classes 20 to 39 per cent susceptible, only 2 caused infection of other children; in classes 40 to 59 per cent susceptible, less than half the exposures caused other cases. But in classes over 60 per cent susceptible only 3 of 11 exposures failed to result in other cases.

When corresponding susceptibility groups are compared, it is seen that a greater percentage of exposures to measles (table 2) resulted in secondary cases than did those of chickenpox. The cases are largely grouped in classes of lower susceptibility, and therefore, although the pattern is similar, it is less regular in the groups of higher susceptibility. In classes less than 20 per cent susceptible, only 2 of 14 exposures caused further cases, while in classes over 20 per cent susceptible, only a third failed to cause other cases.

In table 3 similar data are given for mumps, though the limited dependence to be placed in the susceptibility grouping has already been mentioned. While the susceptibilities are almost certainly high, and therefore not comparable to those of other diseases, there is no reason to assume that either the irradiated or the unirradiated groups are disproportionately high or low. It is seen that mumps required for spread a higher percentage susceptibility as given by previous clinical attack than did chickenpox. However, since these susceptibilities are almost certainly high, the true percentage may well correspond to those of the other two diseases.

(b) *Outcome of Exposures in Irradiated Classes.*—As is seen by the three tables, the ultraviolet lights increased, in all susceptibility groups and in all three diseases, the chance that an exposure would be negative, that the chain of infection would be broken. I do not consider that these figures represent the maximum benefit to be derived from radiant disinfection. The experiments were exploratory, begun at a time when radiant disinfection of air was a new art, hardly out of the laboratory, and were conducted during a period when technical and administrative problems were being solved.

Comparison of the percentage of negative exposures in the irradiated and unirradiated classrooms shows the difference to be greater in classes of high susceptibility, presumably because in classes of lower susceptibilities sanitary ventilation is ordinarily sufficient to prevent the spread of infection with or without any added effect of disinfection of the air. Moreover, the reduction effected by the lights in productive exposures is, while definite, irregular. Thus, in the case of measles there was actually a higher percentage of negative exposures in the classes 80 to 100 per cent susceptible than in any other group. To those who have followed the experiments closely, this suggests that no one cause has been responsible for secondary cases under the lights, but a number of causes, some preventable, some inherent in the method. Of the latter the most serious is high relative humidity of the air, ultraviolet rays being relatively impotent against micro-organisms suspended in air more than 60 per cent saturated. (Thus the productive exposures to mumps in the 80 to 100 per cent susceptibility group of the Swarthmore school occurred in an early fall outbreak, September–November, before heating the indoor air dried it.) Unavoidable too are the secondary cases when droplet infection is too direct for action of indirect irradiation

to be effective. (In May 1938 a first grade child in an irradiated classroom infected with measles 3 small classmates who sat facing her at a table, no children at other tables being infected.) In the case of exposures preventably productive, that is, "breaks" in technic, inadequate servicing of the lights, either as to cleanliness or in testing deterioration and in replacing burners whose output has fallen, is the most serious administrative problem. Misunderstandings as to the principles on which the lights work play a part, as, for example, when we found the lights of one school draped with autumn leaves and Spanish moss for the Thanksgiving festivities. Again, a first grade outbreak of German measles, 9 little girls infected from another little girl, was apparently due to the acquisition of a playhouse within the schoolroom—reproducing in miniature the exact situation the lights were designed to prevent.

SUMMARY

1. The school ventilation standard of 30 cubic feet of air per minute per child is both difficult to attain and inadequate to prevent classroom spread of chickenpox and measles except in relatively immune classes (less than 40 per cent susceptible to chickenpox, less than 20 per cent susceptible to measles).

2. Radiant disinfection of air can be substituted for actual air replacement. In the experiments reported here, the ultraviolet lights increased, in all susceptibility groups and in the three diseases tested—chickenpox, measles and mumps—the chance that an exposure would be negative.

PENICILLIN IN THE TREATMENT OF CHRONIC INFECTIONS OF THE LUNGS AND BRONCHI

AN ANALYSIS OF NINETY-THREE CASES

MAJOR EARLE B. KAY

AND

LIEUTENANT COLONEL RICHARD H. MEADE JR.
MEDICAL CORPS, ARMY OF THE UNITED STATES

Penicillin is the most effective and least toxic antibiotic in general use today. As with all new chemotherapeutic agents, the initial widespread use of penicillin will become more completely defined as its field of usefulness becomes more fully understood. The value of penicillin in the treatment of acute medical and surgical infections is well established. Only by clinical investigation can its value be determined in the treatment of chronic diseases. Chronicity in pulmonary infection introduces factors not present during the acute stage. The presence of complicating mechanical factors such as tissue destruction, fibrosis, avascularity and bronchial occlusion all influence the efficacy of penicillin therapy. Furthermore, chronic pulmonary infections have a varied bacterial flora, and some of the organisms may not be penicillin sensitive. In contrast to the unparalleled value of penicillin in the treatment of acute pulmonary infections, it is of more limited value in the treatment of chronic pulmonary and bronchial infections.

Ninety-three patients with chronic infections of the lungs and bronchi were treated with penicillin. Forty-five of these patients had bronchiectasis, 17 had lung abscesses, 6 had suppurative pneumonitis, 19 had chronic bronchitis and 5 had fungous infections. The

From the Section of Thoracic Surgery, Kennedy General Hospital, Memphis, Tenn.

results of penicillin therapy in the treatment of these patients will be presented and the indications for penicillin will be discussed. This group is of further interest because the patients with bronchiectasis and chronic bronchitis were treated first by intramuscular and later by intratracheal penicillin. As a whole, the greater the degree of permanent tissue destruction and infection, the less benefit was derived from penicillin. This is demonstrated by the partial or transitory results obtained in advanced bronchiectasis, pulmonary suppuration and chronic lung abscesses as contrasted with the excellent results obtained in chronic bronchitis and minimal bronchiectasis. Penicillin has been found to be of value in the treatment of acute exacerbations with increased toxicity, superimposed attacks of bronchopneumonia, chronic bronchitis, minimal bronchiectasis and advanced bronchiectasis too widespread for pulmonary resection. It is also of value in preparing the patient for operation, as an adjunct to surgery making possible operative intervention otherwise impossible and in decreasing the postoperative complications. Benefit derived from penicillin therapy may be only transient; consequently operative intervention when indicated should not be withheld because of a false sense of security.

BACTERIAL FLORA FOUND IN CHRONIC PULMONARY AND BRONCHIAL INFECTIONS

The bacterial flora found in chronic infections of the lungs and bronchi are varied. All of the patients had bronchoscopic examinations. Specimens were obtained for culture and for penicillin sensitivity determinations. No single organism appeared to be etiologically responsible. Cultures showed a combination of organisms with one organism predominating. The bacteria found in chronic bronchitis were similar to those found in bronchiectasis. The most common organisms isolated were alpha, beta and gamma hemolytic streptococci, *Staphylococcus aureus* and *Pseudomonas aeruginosa*. Less frequently found were *Escherichia coli*, *Aerobacter aerogenes* and *Proteus vulgaris*.

Anaerobic streptococci, fusiform bacilli and spirochetes (*Borrelia vincenti*) were more commonly found in patients with chronic lung abscesses and pulmonary suppuration. The streptococci were considerably more sensitive to penicillin than were the staphylococci. Eighty per cent of the streptococci were sensitive to 0.1 Oxford unit or less of penicillin. The other 20 per cent were susceptible to 1 Oxford unit or less. This may be compared to the greater resistance of staphylococci to penicillin. Only 44 per cent of staphylococci were inhibited by 0.1 unit or less and 37 per cent required more than 100 units of penicillin. The coagulase negative staphylococci were found to be more sensitive to penicillin therapy than the coagulase positive organisms. The sensitivity of bacteria to penicillin appeared to vary considerably according to the location of the infection and the type of infection from which they were isolated. Similar bacteria cultured from wounds (mainly battle casualties) showed far greater penicillin resistance than those cultured from bronchi. Many of both groups had had previous penicillin therapy.

PENICILLIN IN THE TREATMENT OF BRONCHIECTASIS

Penicillin is of no permanent value in the treatment of advanced bronchiectasis. Bronchiectasis is a chronic disease characterized by sepsis, cough, sputum, varying degrees of debility and repeated attacks of broncho-

pneumonia. There is bronchial and bronchiolar destruction, dilatation and chronic infection. The degree of disability is largely dependent on the degree of sepsis, which in turn is dependent on the adequacy of bronchial drainage. Penicillin is of considerable value in the treatment of the recurrent pneumonic episodes as well as in decreasing the amount of sepsis and toxicity during the interval stages. It frequently decreases the cough and sputum and increases the sense of well being. It occasionally changes the character of the sputum. However, as soon as the penicillin is discontinued these symptoms may recur. Advanced bronchiectasis is the end stage of a destructive process characterized by replacement of the normal bronchial architecture by less specialized tissue. The ciliated columnar epithelium is replaced by a nonciliated, cuboidal or squamous epithelium. The normal elastic and smooth muscle fibers are replaced by scar tissue. The mucous membrane surface is frequently ulcerated and the bronchial wall replaced by granulation tissue. Because of the loss of the normal cleansing action of the bronchial tree due to the loss of the ciliary action of the mucous membrane and the peristaltic action of the bronchial wall, stasis of exudate and resulting infection occur. The pathologic structure of bronchiectasis explains the chronic state of sepsis and its recurrent periods of exacerbation. Penicillin is only of transient value in the treatment of this sepsis and is no assurance against the recurrence of infection.

During the past year over a hundred patients with bronchiectasis have been treated. Of these, 45 patients with suggestive histories of bronchiectasis were treated with intramuscular penicillin for bronchopneumonia at other hospitals prior to admission. Excellent results were obtained. However, a productive cough and some degree of sepsis persisted. Bronchograms substantiated the diagnosis of bronchiectasis. Because of the gratifying results obtained during the period of acute exacerbation, intramuscular penicillin usually in the

Fig 1.—Extent of 'acicular bronchiectasis'

dosage of 25,000 units every three hours was continued for one to two months in most of these patients and as long as three months in 4 patients. The results obtained were intangible and difficult to analyze. However, it was felt that the majority obtained some benefit. In some patients the sputum decreased and changed in character. Others appeared to raise more sputum. Most patients felt that they were generally stronger and that their appetites were better. One third of the patients noted no improvement. Most of the benefit was noted within the first several weeks of treatment, and thereafter there was little change. Even though improvement was noted, some symptoms of sepsis and a productive cough persisted. Three to four weeks after the penicillin was

stopped symptoms became aggravated. No patient with advanced bronchiectasis appeared to obtain any permanent benefit from intramuscular penicillin. These patients had advanced bronchiectasis that only pulmonary resection by lobectomy could hope to cure. They were then transferred to this center for further treatment. Prior to pulmonary resection a course of intratracheal penicillin was given in an effort to determine any additional benefit that might be derived from this route of administration.

CHRONIC LUNG ABSCESS

Seventeen patients with chronic lung abscess were treated with intramuscular penicillin. The effectiveness of penicillin per se in the treatment of acute lung abscess cannot be determined from our studies, for only those patients who had not responded successfully to previous penicillin therapy were transferred to this center for surgical treatment. The toxicity in 4 patients demanded immediate drainage. The others were again given a trial of penicillin therapy intramuscularly. These patients as a group showed some decrease in toxicity, with a concomitant decrease in the pulse, fever, cough and sputum. Roentgenologically some decrease in the surrounding pneumonitis was occasionally seen. Only 1 patient healed completely. He had shown no previous response to sulfadiazine therapy. A second patient healed almost completely only to have the abscess recur. As a whole there was general symptomatic improvement. However, as soon as therapy was discontinued symptoms recurred. Two patients had acute exacerbations while on treatment (fig. 2).

Fig. 2.—Chronic lung abscess of five months' duration that had an acute exacerbation while on penicillin therapy and required immediate drainage.

The effectiveness of penicillin in the treatment of chronic lung abscess depends largely on the underlying pathologic changes in the lungs. The mechanical factors of tissue destruction, necrosis and gangrene as well as the adequacy of bronchial drainage must be considered. The identity of the causative organisms, their virulence and whether or not they are sensitive to penicillin must be known. These factors determine the clinical course of such infections. It is known that acute lung abscesses with adequate bronchial or bronchoscopic drainage may heal spontaneously. More will respond to sulfonamide and penicillin therapy. However, after a reasonable time has elapsed without healing, further medication with these agents should be supplemented by surgical drainage. There should be no competition of methods in the treatment of lung abscess. One treatment should be an adjunct to the other. Certainly penicillin should be employed even though it does nothing more than to prepare the patient better for operation and to lessen the postoperative complications. Eventually, surgical drainage was employed in all except 1 of these cases.

SUPPURATIVE PNEUMONITIS

Six patients with suppurative pneumonitis were treated with intramuscular penicillin. Four of these patients were treated elsewhere during the acute phase but progressed to chronic suppuration in spite of the penicillin therapy. Even though penicillin did not prevent or cure the pulmonary suppuration, it did decrease the degree of toxicity as well as promote symptomatic improvement. From this standpoint alone penicillin appeared to be of value. Most of these patients had been sick from six to twelve months prior to admission and had had two to four courses of penicillin therapy. When the extent of pulmonary destruction and infection is realized, the failure of chemotherapy alone is readily understandable. When the patient reaches the peak of improvement with penicillin, surgical therapy in the form of pulmonary resection or drainage is indicated. Four of these patients were cured by pulmonary resection and 2 had surgical drainage.

FUNGOUS INFECTIONS

Fungous infections of the lung may be primary or secondary. It is not uncommon to find fungi in the sputum of patients having such debilitating diseases as secondarily infected carcinomas, pulmonary suppuration or chronic lung abscesses. They are frequently found in company with spirochetes and fusiform bacilli. The fungus may be saprophytic and be of no clinical significance. When the fungus is the predominating organism causing the infection, considerable gravity exists because of resistance to therapy.

Five patients with fungous infections of the lungs have been treated with penicillin. Two had coccidioidomycosis, 2 actinomycosis and 1 patient had *Monilia albicans* infection. The patients with coccidioidomycosis and *Monilia albicans* infection had no apparent benefit from intramuscular penicillin. There was no change in the clinical course or the roentgen appearance of the lungs.

Actinomyces bovis is considered sensitive to penicillin therapy. Two patients with chronic pulmonary suppuration had *Actinomyces* cultured from bronchoscopic specimens taken from the affected lungs. Other organisms also were present, but the predominant organism appeared to be *Actinomyces*. The onset of the disease in these patients was insidious, the course progressive and characterized by periodic episodes of acute exacerbation. They were debilitated and septic and had a foul productive cough. Both patients had been previously treated with long courses of sulfonamide and penicillin with only transient benefit. After admission to this hospital these drugs were again employed. If drug therapy was stopped, toxicity soon increased, only to be relieved again after four to six days of chemotherapy. Penicillin appeared to be more effective than the sulfonamides, but the combination of the two was most effective. Though partial symptomatic improvement resulted with chemotherapy, no change in the pulmonary suppuration was noted roentgenologically. Apparent cure by pulmonary resection in combination with chemotherapy resulted in these 2 patients.

CHRONIC BRONCHITIS

The chronic bronchitis group comprised 19 patients. It included patients with ulcerative tracheobronchitis following viral and pyogenic infections as well as hyper-

plastic, asthmatic and catarrhal bronchitis. These patients had had numerous hospitalizations for recurrent bronchopneumonia, productive cough and varying degrees of disability over a period of years. Most of them had been treated at one time or another with intramuscular penicillin, with some benefit. Bronchograms failed to show any evidence of bronchiectasis. Though these patients had shown some response to intramuscular penicillin, dramatic improvement was noted following its intratracheal use. The course of the bronchitis following intratracheal penicillin was followed by periodic bronchoscopic examinations. The use of intratracheal penicillin in the treatment of chronic bronchitis and bronchiectasis will be discussed.

'INTRATRACHEAL' PENICILLIN

Until recently only three routes of penicillin administration were available, the intravenous, the intramuscular and the local application. Penicillin in its oral form had not been perfected. The intramuscular or intravenous administration of penicillin over any period of time is associated with considerable discomfort to the patient, necessitates continuous hospitalization and demands considerable nursing time. For these reasons and because of the fact that the infection in bronchitis is relatively superficial it was felt that the daily intratracheal application of penicillin would be of value. The first patients on whom this was tried had viral or pyogenic ulcerative tracheobronchitis. Bronchoscopy was done before, during and following intratracheal therapy. Complete healing of the ulcerative bronchitis was noted in several weeks' time, in contrast to several months' time with the usual forms of treatment.

Initially, 3 to 5 cc. of a saline solution of sodium penicillin containing 250 Oxford units to the cubic centimeter was used. This, at that time, was the accepted concentration of penicillin for local application. This concentration was later increased to 1,000, 5,000 and finally to 10,000 Oxford units to the cubic centimeter with no apparent irritating effect to the patient's tracheobronchial mucosa. It was impossible for the patient to tell what concentration was being applied. With this concentration as much as 30,000 to 50,000 units of penicillin can be applied daily or as desired to the tracheobronchial tree at one application. As much as 600,000 to 1,000,000 Oxford units of penicillin can be applied within a three week period. This is felt to be an effective dosage. A blood penicillin level as high as 0.03 Oxford unit as determined by the multiple tube dilution method using a sensitive strain of *Staphylococcus aureus* as the indicator organism can be obtained within thirty minutes following the intratracheal administration. With increasing concentration, increasing benefit was obtained. Those patients not relieved by the smaller concentration obtained relief with the larger dosage.

METHOD OF APPLICATION

The method of administration is the introduction of the penicillin directly through the vocal cords by means of indirect laryngoscopy and a flexible laryngeal cannula. The penicillin is injected at the end of expiration, thus necessitating an inspiration before coughing is possible. Many of the patients can take the intra-

tracheal penicillin without coughing. The patient leans to the affected side during administration. If need be, penicillin can be injected on both sides. On coughing, patients can detect a penicillin taste as long as four to six hours after administration.

Most patients with chronic bronchitis believed that more benefit was obtained from the intratracheal than from the intramuscular use of penicillin. In patients with chronic bronchitis and minimal bronchiectasis almost complete relief of symptoms was obtained in two to four weeks' time. Every patient with bronchitis stated that "definite improvement had been obtained. Patients with asthmatic bronchitis secondary to an intrinsic bacterial factor were also considerably improved. They noted a decrease in the cough and sputum, and relief from wheezing and the sensation of tightness in the chest. These patients felt that they were freer from symptoms than at any time since the onset of their disease." Several of these patients had been previously treated with intramuscular penicillin with some benefit, but they felt that the daily intratracheal penicillin was more effective. Patients with asthma obtain no relief from penicillin, and some may show sensitivity with resulting asthmatic attacks.

Forty-five patients with bronchiectasis were similarly treated. Thirty-eight patients had advanced bronchiectasis, and 7 patients minimal bronchiectasis. The 7 patients with minimal bronchiectasis obtained almost complete relief of symptoms. Two thirds of the patients with advanced bronchiectasis felt that there had been definite improvement from such treatment, but not to the extent noted in the less advanced conditions. Improvement in symptoms did not occur until after four or five days of treatment.

Some of the bronchiectatic patients noted less sputum and cough. Others stated that they could raise more easily and that there was an increase in sputum. Several improved to the extent that while on treatment the symptoms had so subsided that they felt lobectomy was not necessary. However, these were patients with advanced bronchiectasis and, after penicillin was discontinued, symptoms soon recurred and operative intervention was welcomed. The degree of improvement was usually, but not invariably, proportional to the severity of the disease and the acuteness of the infection.

Those patients with advanced bronchiectasis with severe secondary bronchitis were also treated preoperatively with intratracheal penicillin. They too noted alleviation of symptoms and considerable reduction in the productive cough. Healing of the secondary bronchitis was noted bronchoscopically. It was felt that the intratracheal penicillin was of particular value in the treatment of chronic bronchitis, in minimal bronchiectasis, in advanced inoperable bronchiectasis and in the preoperative preparation of lobectomy patients.

SUMMARY

The clinical use and value of penicillin in the treatment of 93 patients with chronic infections of the lungs and bronchi were studied. Penicillin is of unparalleled value in the treatment of acute pulmonary infections, but as chronicity develops it becomes less effective. Chronicity in pulmonary infections introduces factors not found during the acute stage which influence the

efficacy of penicillin therapy These are the mechanical factors of tissue destruction, fibrosis, avascularity and bronchial occlusion

Routine bronchoscopy was done before, during and after penicillin therapy The course of the disease and the efficacy of treatment were noted Bronchoscopic specimens were obtained for culture and penicillin sensitivity of the organisms isolated Even though the sputum decreased in amount and evidence of sepsis diminished, the bacterial flora was not appreciably affected

Penicillin appears to be of value in the treatment of acute exacerbations of chronic infections, superimposed attacks of bronchopneumonia, chronic bronchitis, minimal bronchiectasis and advanced bronchiectasis too widespread for pulmonary resection It is also of value in preparing the patient for operation, as an adjunct to surgery making possible operative intervention otherwise impossible, and in decreasing the post-operative complications

Penicillin is of no permanent value in the treatment of advanced bronchiectasis Pulmonary resection should not be withheld when indicated because of the false sense of security resulting from temporary benefit

In the treatment of pulmonary suppuration, chronic lung abscesses and fungous infections the chief value of penicillin is its ability to decrease the general manifestations of toxicity, to promote symptomatic improvement and to prepare the patient for operative intervention

The intratracheal administration of penicillin in the treatment of chronic bronchitis and bronchiectasis appeared to give more benefit in many cases than the intramuscular route As much as 30,000 to 50,000 Oxford units of penicillin can be applied daily in one application to the tracheobronchial tree Excellent results were obtained in patients with chronic bronchitis and minimal bronchiectasis by this method

It is of interest to note that the pathologic examination of 75 lobectomy specimens failed to show any appreciable difference in the degree of infection in 25 specimens in which penicillin had not been employed preoperatively, as compared to 50 specimens in which penicillin had been used

Pulmonary resection for chronic sepsis with present day technics, anesthesia and chemotherapy is a safe procedure and can be recommended without hesitation There was only 1 mortality out of 100 patients having lobectomy by us, an operative mortality of 1 per cent, which compares favorably with any other operative procedure

Mental Hygiene in Later Maturity—Aging is a normal biologic process or a series of processes, but it is usually hastened, exaggerated or modified in some fashion by abnormal or disease trends incident to life in a quantitative or qualitative relationship trends which are sometimes not readily distinguished from normal senile developments However, senility is the favorable time of life for the development of several serious diseases, diabetes mellitus and cancer, which complicate the general problem in specific ways involving any mental hygiene program that may be under consideration—Lewis, Nolan D C *Mental Hygiene in Later Maturity*, from *Mental Disorders in Later Life* edited by Oscar J Kaplan, Stanford University Press, 1945

DISTORTIONS OF THE GASTRIC FEEDING REFLEX

ASSOCIATED WITH EXTRAGASTRIC PATHOLOGIC CONDITIONS THEIR CLINICAL SIGNIFICANCE

P B WELCH, M.D.
MIAMI, FLA

The walls of the normal fasting stomach are maintained in coaptation by a state of tonus of its muscular coats, with recurrent periods of superimposed peristaltic activity With the first taste of food there follows an immediate relaxation of gastric tonus with usually a fairly complete inhibition of peristalsis, resulting in a widening of the gastric lumen to accommodate the expected food ingesta This is the normal gastric feeding reflex (fig 1)

In the presence of various types of extragastric pathologic change, usually intra-abdominal or pelvic, this normal feeding reflex is distorted Instead of relaxation there is an immediate increase in tone, with or without superimposed peristalsis The degree of distortion roughly parallels the intensity of the sensory or psychic stimuli (fig 2A and B) and is not influenced by the degree of acidity of the gastric secretions (table 1)

There apparently was no relationship between the degree of acidity and the distortion of the reflex

These distortions of the normal gastric feeding reflex are associated with characteristic symptoms referable to the stomach (table 2) and vary in severity with the degree of distortion of the feeding reflex (fig 2B) Other symptoms are usually associated and vary with the site of the pathologic condition initiating them, such as pain in the right upper quadrant in the presence of gallbladder disease, pain or distress in the flanks or pelvis associated with urologic or pelvic pathologic change, and so on But the symptoms referable to the distorted gastric feeding reflex have certain definite characteristics usually manifesting themselves by distress, a feeling of fullness, eructations, heartburn or actual pain in the epigastrium, left upper quadrant or substernal region They all have one common characteristic and that is their immediate occurrence on the ingestion of food

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago June 15 1944

These symptoms are usually ascribed by the patient to "gas" and probably constitute the most common abdominal symptom complex encountered.

An understanding of the motor changes in the stomach and their mode of production, associated with these

Fig 1—This tracing, of stomach of Mrs. M., shows the normal relaxation of the gastric musculature which occurs immediately with the ingestion of food. The patient was fed at the point indicated by the arrow. It will be noted that there was an immediate inhibition of peristalsis and relaxation of tone, with a gradual resumption of tone and peristaltic activity.

characteristic symptoms, is of inestimable value in the management of these otherwise, sometimes difficult clinical problems, as shown in the case of Mrs. J., who had been attending the outpatient clinic for many months with vague postprandial epigastric distress and irregular, usually constipated bowel movements. These symptoms had been attributed to a pernicious anemia,

A

B

Fig 2—4, patient S. F., with irritable colon moderate distortion of gastric feeding reflex, peristalsis inhibited, no normal relaxation. At point marked by arrow a shredded wheat biscuit with milk was given. Tracing shows very active peristalsis in the fasting stomach with inhibition of peristalsis with feeding and for several minutes thereafter, with a rapid resumption of peristalsis and tone, this being a moderate distortion of the gastric feeding reflex associated with a moderate stimulation from the colon. B, Mrs. D., with chronic appendicitis pronounced distortion of gastric feeding reflex with considerable increase in tone. Tracing shows decided inversion of the gastric feeding reflex with much increase in tone and superimposed peristalsis, symptom severity being 4 plus and distortion of the feeding reflex being 4 plus. At point indicated by arrow a shredded wheat biscuit with milk was given.

with complete achylia after histamine stimulation and a typical atrophic gastritis demonstrated gastroscopically. Her pernicious anemia responded satisfactorily to treatment, but her abdominal complaints continued.

A repeated complete physical examination revealed only a moderate number of internal hemorrhoids, a moderate pectinitis and an associated well defined spasm of the anal sphincter.

A kymographic tracing before correction of her anal pathologic condition with an intragastric balloon was made after a fourteen hour fast. This tracing (fig. 3 A) showed a moderate distortion of the feeding reflex, comparable to the severity of her symptoms. A hemorrhoidectomy was performed, her abdominal symptoms completely disappeared, and five weeks later another tracing was made (fig. 3 B) which showed a normal gastric response to feeding as the result of correction of the pathologic condition in the anus.

Another patient, Mrs. M., complained of vague abdominal symptoms consisting of epigastric pressure and distress and nausea and vomiting. A complete survey, including gastrointestinal fluoroscopy and radiography, complete physical examination and routine laboratory studies, failed to reveal the cause of her distress. A urologic investigation was made and a

A

B

Fig 3—A, tracing of stomach of Mrs. J., who was fed at time interval indicated by arrows. Very rapid gastric peristalsis associated with hemorrhoids and an achylia and pernicious anemia. There is a moderate distortion of the gastric reflex consisting of a lack of inhibition of peristalsis and a slight increase in tone. B, tracing on the same patient showing a normal gastric feeding reflex five weeks after a hemorrhoidectomy. Feeding of meat and vegetables was given at interval indicated by arrows.

stricture of the urethra and left ureter was found. A kymographic tracing of her stomach was made in the usual manner (fig. 4) and showed an inversion of the gastric feeding reflex, with almost complete obliteration of the gastric lumen. Correction of the urologic condition resulted in complete subsidence of her abdominal symptoms. In this case, unfortunately, after subsidence of symptoms we were unable to obtain another gastric tracing.

Kymographic tracings were made on a dog's stomach, through a permanent gastric fistula, before and after a left sided ureterostomy. Figure 5 A shows a normal gastric feeding reflex before ureterostomy, and figure 6 B shows the distortion of the gastric feeding reflex after trauma to the left ureter. It will be noted that the distortion seen in this tracing of the dog's stomach is almost identical with that shown in the tracing on the human stomach (fig. 4) with pathologic change of the left ureter.

Kymographic tracings were made of 19 human stomachs with varying types of extragastric pathologic changes as outlined in table 2. In all these cases there was a fairly constant qualitative relationship between the intensity of symptoms and the degree of distortion of the feeding reflex. In 4 cases the sensory stimulation was apparently greater than the degree of distortion. This was in part explained by the patient's susceptibility to pain.

It is beyond the scope of this presentation to discuss fully the distortions of the gastric feeding reflex initiated by psychic stimulation. However, the experi-

It is evident from a wide clinical experience and the studies made on the motor activity of the stomach that, in the presence of the syndrome of postprandial epigastric distress, fulness, pressure, burning or pain and eructations, the stomach is almost the last place to look for pathologic changes. When this syndrome is present it is an immediate challenge to one's diagnostic acumen and constitutes a definite indication for a complete clinical investigation to identify the source of the extragastric stimuli producing the changes in the motor function of the stomach, which may arise from any source from the psyche to the rectum.

TABLE 2.—Correlation of the Diagnosis, Intensity of Symptoms and Degree of Inversion of the Reflex

Case	Diagnosis	Abdominal Symptoms	Symptom Intensity	Degree of Inversion
1	Chronic appendicitis	Postprandial epigastric distress, also right upper quadrant distress	4 plus	4 plus
2	Chronic appendicitis	Postprandial epigastric burning, eructations	2 plus	3 plus
3	Chronic appendicitis; duodenal ulcer	Postprandial epigastric pressure, eructations, abdominal soreness	3 plus	4 plus
4	Chronic appendicitis; duodenal ulcer	Postprandial epigastric distress, right lower quadrant soreness	2 plus	3 plus
5	Duodenal ulcer	Epigastric soreness, eructations	3 plus	4 plus
6	Chronic duodenal ulcer; moderate stenosis	Soreness left upper quadrant, eructation; occasional vomiting	3 plus	4 plus
7	Duodenal ulcer; cholecystitis	Severe epigastric and right upper quadrant pain	4 plus	4 plus
8	Hypertrophic hepatitis	General epigastric pain, eructations	4 plus	4 plus
9	Colon stasis; irritable colon; overeating	Epigastric pressure, eructations	2 plus	2 plus
10	Glossitis subacute; hemorrhoids; irritable colon	Epigastric burning	3 plus	2 plus
11	Pronounced colon stasis; irritable colon	Epigastric gnawing pain	1 plus	1 plus
12	Hemorrhoids; irritable colon; pronounced stasis	Epigastric fulness and pressure	2 plus	1 plus

16	Pernicious aneur	Epigastric distress and eructations	1 plus	2 plus
17	Urethral and ureteral stricture	Epigastric fulness, distress; nausea and vomiting	3 plus	4 plus
18	Achlorhydria; gastric atony	Symptom free	None
19	Achlorhydria	Symptom free	None

ence of Mrs. A. rather theatrically demonstrates this relationship. She was in perfectly normal health and completely symptom free. She sought shelter under a tree from a sudden rain squall. The tree was struck by lightning and she was knocked to the ground but sustained no bodily injuries. From that time on she was emotionally unstable and promptly developed postprandial epigastric burning, fulness, pressure and eructations. Most careful and repeated surveys failed to reveal any organic lesion except an achylia gastrica. A kymographic tracing showed a well defined inversion of the feeding reflex.

Fig. 4 (Mrs. A., hyperperistalsis).—Well defined distortion of the feeding reflex in the human stomach associated with urethral stricture and left ureteral stricture. Arrows point to feeding with 4 ounces of milk and potato gruel.

Clinically, emotional stresses are frequently encountered with the syndrome of postprandial epigastric distress. The common association of anorexia with grief, and the loss of relish of food with anxiety, hostility or resentment are common experiences.

Stewart and Harold Wolf,¹ in observations through a permanent gastrostomy, have shown that in the presence of a psychic state of hostility and resentment there is an increased gastric motility associated with gastric hyperemia and hyperacidity.

1. Wolf, Stewart, and Wolf, Harold, G.: Human Gastric Function: An Experimental Study of a Man and His Stomach, London, Oxford University Press, 1943, pp. 113-119.

SUMMARY AND CONCLUSIONS

The normal gastric feeding reflex consists of an immediate relaxation of the muscular walls of the stomach on the first taste of food.

In the presence of extragastric abdominal, pelvic or psychic pathologic change this reflex is distorted. Instead of relaxation with the ingestion of food there is an immediate increase in tone or peristaltic activity, or both.

Fig. 5.—A, stomach tracing of dog, showing a normal gastric feeding reflex. At the point indicated by the arrow a feeding was given of ¼ pound of raw beef. B, tracing of same dog's stomach after a left ureterostomy, which shows a decided distortion of the feeding reflex. The dog was fed at the point marked by the double arrows. A great deal of similarity will be noted between the tracing of the dog and that of the human stomach shown in figure 4, both associated with a urologic pathologic condition.

The degree of distortion of the feeding reflex is roughly proportional to the intensity of the symptoms and is not influenced by the degree of acidity of the gastric secretions.

These distortions of the feeding reflex are almost invariably associated with a characteristic group of

symptoms initiated by eating and consisting of a feeling of fullness, pressure, distress, eructations, heartburn or actual pain in the epigastrium, left upper quadrant or substernal region.

These symptoms can be permanently relieved only by finding and correcting the extragastric pathologic condition producing them, as exemplified in the cases reported.

The abdominal symptom complex associated with distortions of the gastric feeding reflex is the most common one encountered by the gastroenterologist and the general practitioner. An understanding of these changes in the muscular activity of the stomach associated with extragastric pathologic conditions has been of inestimable value in rationalizing otherwise difficult clinical problems

ABSTRACT OF DISCUSSION

DR. MORTON J. OPPENHEIMER, Philadelphia: There is abundant clinical evidence in support of Dr. Welch's views. Barron and his associates reported gastric hypermotility associated with epigastric distress. They concluded that sensory nerves of the stomach were stimulated by the abnormal motor activity; after cholecystectomy, gastric hyperactivity was recorded when patients complained early of gas pains and later of excessive hunger. As in Dr. Welch's patients, preoperative apprehension was found concomitant with increased motility. This increase or the inhibition depends on the preexisting tonus level of the stomach. Herniorrhaphy inhibited gastric motility followed by increased activity. The distention and inhibition during operation were considered to be the stimulus for the subsequent increased peristalsis, with resulting gas pains. Benign duodenal ulcer producing pyloric obstruction of short duration has also been shown to cause gastric hypermotility, which was initiated by the ingestion of food and abolished by atropine. Gastric motility recorded by experimental balloon methods may at times augment duodenal hyperactivity in duodenal ulcer. Croton oil applied to the mucosa of the proximal colon, appendix and gallbladder, or distention of these same viscera, augments activity of the stomach in experimental animals. This has been confirmed in the case of the colon for patients exhibiting epigastric distress. Distention of the ureters above 35 mm. of mercury caused gastric inhibition or hypermotility, while gallbladder intracystic pressures above 50 mm. of mercury was followed by loss in gastric tone and changed type of contraction with hypermotility; furthermore, urinary bladder distention caused gastric inhibition. The sensory pathway for this last was in the presacral nerve. Youmans and his associates showed that gastric tonus and motility decreased during mild mechanical stimulation of the anal canal and rectum. This was not prevented by vagotomy or adrenal demedullation but disappeared after splanchnic or lumbar chain resection; moreover, a mediator reflexly released at the abdominal sympathetic nerve ends during rectal stimulation was found to enter the blood stream and inhibit the intestine. Also, under other circumstances, increased intrarectal pressure may inhibit gastric tonus and motility. Brody, Werle, Meschan and Quigley showed that, even after vagotomy, swallowing food produces transient gastric inhibition followed by phasic changes of greater magnitude. Thus it may be seen that experimental evidence has furnished an ample framework for the support of Dr. Welch's views.

DR. PAUL B. WELCH, Miami, Fla.: Dr. Oppenheimer has made reference to the inhibition of gastric motility by stimuli arising from extragastric viscera. This inhibition is not confined to the stomach but occurs throughout the entire digestive tube. Adynamic ileus frequently occurs with kidney colic, simulating acute mechanical intestinal obstruction. In previous studies of the viscerovisceral reflexes, with a balloon introduced in the colon, reflex disturbances in the colon motility were initiated by trauma to the right ureter. There was first inhibition of motor activity, followed by a prolonged and gross increase in muscle tone and peristalsis in the colon. It is probable that the same mechanisms operate to cause the distortions of the feeding reflex in the stomach as in the rest of the digestive tract.

Clinical Notes, Suggestions and New Instruments

A DEVICE FOR PROTECTING THE SKIN AND COLLECTING FLUID FROM FISTULAS

OR FOR KEEPING PENICILLIN SOLUTION IN CONTACT WITH A WOUND

LIEUTENANT COMMANDER GEORGE CRILE JR. (MC), U.S.N.R.

It is sometimes desirable to treat open wounds by application of penicillin solution. In cases when a penicillin saturated pack cannot be applied in such a way as to reach all the recesses or when the contour of the wound is such that it will not hold the solution, a device for sealing the entrance of the wound to retain the solution is of value.

In patients with external biliary fistulas the constant saturation of the dressings with bile makes the patient wet and uncomfortable. The same is true in the case of fistulas of

Fig. 1.—Suction apparatus for biliary fistula.

the small intestine, and in addition secretions digest the skin if it is not protected. There is often a need for a device which will collect the secretions and at the same time protect the skin.

The need for some way to collect the fluid and protect the skin was quite urgent in the case of a nearly complete small intestinal fistula. The skin was not as yet eroded and it appeared as though a piece of rubber dam could be cemented to the skin around the opening in such a way as to protect the skin and at the same time allow the secretions to be collected. A catheter was first placed through a tiny hole in the center of a broad piece of rubber dam. The rubber dam was next covered with rubber cement and the skin similarly treated. The dam was placed over the fistula in such a way as to allow the catheter to lie in the wound, and the other end was attached to a Wangenstein suction apparatus. The suction successfully carried away the juices and kept a negative pressure

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

against the rubber dam, so that it did not pull away from the skin. The patient was grateful to be able to lie in any position, to be dry and to have his skin protected from the painful digestion of the intestinal juices.

This device has been used on several small intestinal fistulas with satisfactory results. It is applicable to biliary fistulas if the patient is more comfortable than with the dressings wet or if it is desired to collect or measure the bile. It can also be used on any open wound or on any localized skin lesion in which it is desirable to keep a solution of penicillin in contact with the lesion for a considerable length of time. The penicillin can be introduced through the catheter, withdrawn periodically, and more of the solution inserted. If negative pressure and frequent irrigations are not required, the catheter can be eliminated and the penicillin injected by means of a small needle.

PRECAUTIONS

1. Make the hole in the dam very small and avoid wrinkling of the dam. Leaks tend to occur along wrinkles.
2. Cut several large holes in the catheter so that they will not become plugged with mucus or all lie against the side of the wound.
3. Clean the skin thoroughly with ether to remove all grease and moisture.
4. Put a very thin coat of cement on both skin and rubber and let both coats dry before applying the rubber. If applied wet or if the cement is too thick it will not stick well.

Fig. 2.—Suction apparatus used in open wound.

5. Secure the corners and sides of the dam with hemostats to prevent it from folding up when the cement is applied.
6. Be certain to eliminate all wrinkles which can act as potential leaks.
7. Attach suction immediately and never allow the suction to stop lest the fluid under pressure dissect the rubber up from the skin.

ADVANTAGES

1. The apparatus collects fluid for analysis or measurement.
2. It renders dressings unnecessary.
3. It can utilize Wangensteen suction instead of water or mechanical suction.
4. It keeps the patient comfortable and dry.
5. It allows the patient to change position.
6. It protects the skin.
7. The negative pressure appears to hasten the obliteration of an abscess cavity.

DISADVANTAGES

1. The device is not applicable after the skin is irritated and discharging serum.
2. It requires changing every five or six days as the old skin is desquamated.
3. It requires careful supervision of the suction apparatus.
4. It is not always applicable to wounds which are so small that the holes in the catheter are blocked by being in constant contact with all sides of the wound.
5. The skin is sometimes sensitive to rubber cement and blisters.

GASTROSTOMY IN POLIOMYELITIS

THEODORE F. HILBISH, M.D.

Surgeon, U. S. Public Health Service, U. S. Marine Hospital
FORT STANTON, N. M.

Pharyngeal paralysis associated with difficulty in swallowing is not unusual in bulbar poliomyelitis, but this condition seldom persists more than a few days. Wilson¹ states that "difficulty in swallowing is transitory and the worst is usually over in one week." Physicians treating large numbers of poliomyelitis cases have, however, experienced situations on rare occasions when pharyngeal paralysis has persisted well over the week.

It has been shown that if life can be sustained through the acute phase of the disease there is practically always a 100 per cent recovery of the pharyngeal muscles. As a rule tube feeding is not too difficult, but dangers associated with this procedure are always present and must be avoided whenever possible. The three main hazards are (1) aspiration of mucus or vomitus with resulting bronchial obstruction and sudden cessation of respiration, (2) choking attacks with temporary severe anoxemia and cyanosis and (3) excessive fatigue. In the case reported here it was the latter which necessitated a gastrostomy as a life-saving measure.

Review of the literature reveals a surprising absence of case reports on pharyngeal paralysis. Brahdry and Lenarsky² reported 5 cases in which pharyngeal paralysis persisted from twenty-one to seventy-one days. The longest time interval found was in a case reported by Miller,³ in which there was a complete inability to swallow for a period of eighty-six days. In all instances reported in the literature, nutrition was maintained by intravenous, subcutaneous and rectal routes, as well as by gastric gavage. After a thorough perusal of writings, not a single report was found in which a gastrostomy was performed to maintain nutrition. For this reason the present case was considered of sufficient interest to report.

REPORT OF CASE

History.—M. A. C., a white schoolgirl aged 12, was admitted on July 30, 1944 to the U. S. Marine Hospital at Fort Stanton, N. M., complaining of difficulty in swallowing. She first became ill on July 28, at which time she became nauseated, vomited and felt dizzy. The following morning she was seen by a physician because of pain in the head and teeth. Acute sinusitis was considered at that time because of purulent discharge observed from the sinuses. The following evening she was admitted to the hospital with the aforementioned complaints.

The past history was noncontributory. She had had measles, mumps and chickenpox with good recovery. She also had "acute food poisoning" at 6 years of age, following which her eyes had remained "weak." She had a tonsillectomy when 4 years of age but no other operative procedures.

The family history was entirely negative.

Examination.—On admission the patient was acutely ill and toxic. Her temperature was 101.6 F. and pulse rate was 120. There was pronounced nuchal rigidity, with loss of function of the anterior neck muscles demonstrated by complete inability to hold up the head when the shoulders were lifted from the bed. The patient had a decidedly nasal "twang" on speaking and there was a complete pharyngeal paralysis. Administration of liquids resulted in the return of these fluids through the nose. There was some evidence of rigidity of the paravertebral muscles and a diminution of the ankle and knee jerks bilaterally. Chest, heart and other systems were essentially normal. There was no evidence of other muscle involvement at the time of admission.

Laboratory Findings.—The blood count showed 5,000,000 red blood cells, 110 per cent hemoglobin, 12,800 white blood cells with 78 per cent neutrophils, and negative Kahn reaction. Urinalysis showed 1 plus albumin, a few blood cells and 20

to 30 pus cells. A spinal puncture, performed on July 31, revealed a slightly turbid fluid under normal pressure, while studies of this fluid demonstrated 1,250 cells, mostly polymorphonuclears, a 3 plus Pandy test and negative smear and culture for organisms. Spinal tap repeated three days later revealed the cell count to be down to 38 cells, with lymphocytes predominating. The spinal sugar was 62.5 mg. per hundred cubic centimeters and again smear and culture failed to reveal organisms. Repeated urine and blood tests were essentially normal except for gross blood in the urine on one occasion. The blood level for sulfadiazine was 15 mg. per hundred cubic centimeters.

Clinical Course and Treatment.—The patient's temperature rose to 104 F. the day following admission and the patient was irrational. Sodium sulfadiazine was administered on the strength of the laboratory report of 1,250 cells with cloudy fluid and no report of spinal sugar findings. Hematuria was noted the following day and the drug was discontinued. The diagnosis of poliomyelitis appeared to be well established by this time; consequently further sulfadiazine medication was not indicated.

The patient's course was very stormy during the first week of hospitalization. She was confused, disoriented and irrational. Constant attendance was necessary for restraint and for aspiration of the thick glairy mucus which continuously collected in her throat. Her temperature ranged from 99.8 to 104 F. Feeding was accomplished by intravenous and subcutaneous fluids.

The patient complained of pain in the right deltoid muscles on occasion. Muscle spasm was noted of the hamstring muscles, chiefly the right. Increasing evidence of respiratory difficulty was manifested in irregular respiration and transitory apnea. The symptoms suggested spinal involvement along with bulbar poliomyelitis, and arrangements were made to secure a Drinker respirator from the Carrie Tingley Hospital at Hot Springs, N. M., a distance of approximately 150 miles.

On August 4 the patient became cyanotic and developed considerable respiratory difficulty. Caffeine and other respiratory stimulants were administered without benefit. It was not until the patient could be placed in the Drinker respirator that relief and freedom from respiratory difficulty was achieved. She regained normal color and sank into a sleep of exhaustion.

Attempts were made during the first ten days to pass a Levine and Rehfuess tube, but in each instance obstruction was encountered at the lower end of the esophagus. Feeding was continued by intravenous and subcutaneous methods, the rectal route having proved essentially unsuccessful because of inability to retain fluids. The necessity for other means of administering nutrition became increasingly obvious. An ear, nose and throat specialist was called from El Paso, Texas, and a Levine tube was passed under direct vision after considerable difficulty. The patient was weak and exhausted after this ordeal and begged that it be not attempted again. The tube was retained four hours, when it was regurgitated. Again we were faced with the problem of feeding by the intravenous route, which was made difficult because the patient could not be removed from the respirator. Another specialist was called from Albuquerque and this time, after three hours of strenuous effort, a Miller-Abbott tube was passed, leaving the patient in poor condition and obviously unable to stand another such procedure. She had severe pain for twenty-four hours following the passage of the tube. No feedings were given during this interval. The Miller-Abbott tube finally had to be deflated to relieve her pain. Fifteen hundred cubic centimeters of a concentrate mixture containing approximately 3,000 calories was administered daily by the gastric route. The patient's condition improved rapidly and she started to regain her strength.

On August 11 she was removed from the respirator for a short time without experiencing too much difficulty. The time interval outside the respirator was increased steadily, though gradually, during the following days, and on August 14 she was completely removed from the respirator. The patient showed evidence of spasm of both groups of hamstring muscles and some weakness of the quadriceps femoris on the left side. Kenny treatment was begun and continued until spasm was gone. Also on August 14 the stomach tube was vomited and

gastric feedings were of necessity discontinued. She was then nourished by intravenous fluids, with amino acids added to the glucose. It became increasingly difficult to administer fluids by this route owing to sclerosis of the veins. The patient again showed signs of inadequate caloric intake and began to feel weaker and show obvious weight loss. She was now able to remain outside the respirator without respiratory decompensation, although her breathing was irregular when she was asleep.

On August 18 the patient's condition and the necessity for other means of feeding were discussed with the family. A gastrostomy was suggested, since the patient was still completely unable to swallow and since the patient's condition was favorable to allow the procedure at this time. With the family's consent a consultant from Albuquerque was called and a gastrostomy was performed under local anesthesia without difficulty. The patient was returned to her room in good condition and feedings were started immediately. The patient's response to adequate feeding was remarkable. She promptly regained weight and strength. Nine days after the operation the stitches were removed and a clean gastrostomy tube was reinserted. She continued to improve and on August 31 was able to swallow a small amount of fluid for the first time, but with considerable difficulty. The tube was left in place until September 10. By this time she was able to eat solids and drink liquids but had to take both types of food very slowly. Following the removal of the gastrostomy tube on the date mentioned the wound was apposed with flamed adhesive tape. The incision closed rapidly, without a sign of infection.

The patient continued to gain weight and strength and her muscles showed steady improvement. Her neck muscle function returned entirely and there was a rapid return of function to the hamstring muscles, although the hamstring and gastrocnemius muscles bilaterally were still tight. Likewise she still showed partial paralysis of the pharyngeal muscles and of the uvula. She was afebrile and felt fine when discharged from the Marine Hospital on September 20 to report at Carrie Tingley Hospital, where facilities were available for convalescent poliomyelitis care. She was seen at this institution on September 21 and allowed to return home, with instructions to take hot baths, twice daily followed by muscle stretching exercises and to start walking. She was hospitalized at Carrie Tingley Hospital on November 4 for muscle tests and exercises and was discharged on November 21, at which time she was able to walk without calcaneal or Trendelenburg limp. She was able to swallow more easily and seldom strangled.

At the present time the patient reports by letter that she is feeling well and is improving. There is some residual weakness of the left leg with $\frac{1}{2}$ inch difference in circumference as compared to the right leg. She is taking therapeutic exercises and muscle stretching maneuvers. She still experiences infrequent transitory pharyngeal "spasm" but states that she is able to eat at the regular rate. A complete palatal paralysis still persists on the left side.

COMMENT

As mentioned previously, this case, as far as could be ascertained from available literature, represents the first one of poliomyelitis in which a gastrostomy was performed. Some may question the advisability of the procedure, but at the time and with our facilities it seemed the wisest move. It is not intended to suggest a gastrostomy in cases with prolonged inability to swallow. However, after observing such remarkable recovery following the gastrostomy, one wonders if the operation might not be considered in cases in which extreme difficulty is encountered in passing a gastric tube. In view of the increasing and steady return of ability to swallow, it seems highly likely that the obstruction encountered was of a temporary nature, perhaps a "spasm" of the cardiac end of the esophagus. After all, it is known that spasm of numerous skeletal muscles occurs in this disease and it does not seem improbable that such an episode might occur in smooth muscles.

My transfer to another assignment precluded the opportunity for study of the lower esophagus with barium.

SUMMARY

A case was encountered in which a gastrostomy was performed for prolonged inability to swallow, associated with poliomyelitis.

ESCHERICHIA COLI MENINGITIS TREATED WITH
SULFADIAZINEMAJOR PAUL S. STRONG AND LIEUTENANT COLONEL JESSE E. EDWARDS
MEDICAL CORPS, ARMY OF THE UNITED STATES

Instances of meningitis due to the coliform group of organisms are sufficiently rare in adults to warrant the reporting of another case. The majority of the cases described have occurred in infants and children and have usually been associated with infections of the middle ear, the gastrointestinal tract, the urinary tract or the umbilicus.¹ Of 3,178 cases of meningitis due to all types of organisms, Neal² reported only 8 cases due to the coliform group. Stallworthy³ reported 2 cases in adults, one presumably coincidental with intracerebral hemorrhage and the other secondary to extensive suppuration of the liver and biliary tract.

In the case to be presented the meningeal infection resulted from an abscess secondary to a penetrating wound of the sacrum (fig. 1).

REPORT OF CASE

A white soldier aged 24 was wounded in the back by a bullet on June 6, 1944. Emergency first aid treatment consisted of a dry dressing over the wound of entry, morphine, tetanus toxoid and oral sulfadiazine. He was admitted to a general hospital on June 13 complaining of fever and severe pain in the low back region. Sulfadiazine was continued in a dosage of 1 Gm. three times a day. On the third hospital day the temperature fell to normal and the sulfadiazine was discontinued. There was a small amount of purulent drainage from the wound on June 19, but the bullet entrance had healed on the 21st.

The white blood cell count on admission was 5,000 per cubic millimeter, the hemoglobin was 95 per cent (Tallquist) and the

Fig. 1.—Relation of foreign body to subarachnoid space.

urine examination was negative. An x-ray of the lumbar spine and pelvis showed a bullet shaped opacity (0.6 by 2 cm.) in the region of the midportion of the second sacral segment (fig. 2).

On June 21, eight days after his admission to the hospital and fifteen days after he was wounded, the patient complained of severe headache, fever, nausea and vomiting. During the next twelve hours he became irrational, and signs of meningeal infection appeared. A lumbar puncture revealed cloudy fluid with 675 cells, 94 per cent of which were polymorphonuclear neutrophils. The spinal fluid sugar was 10 mg. per hundred cubic centimeters and on direct smear gram negative intracellular organisms thought to be diplococci were present.

Sodium sulfadiazine 5 Gm. was given intravenously, followed by oral sulfadiazine 2 Gm. every four hours. Although the temperature remained elevated, the patient showed considerable improvement at the end of eighteen hours. The improvement was not maintained, and during the next twelve hours he grew rapidly worse and became disoriented. At this time the etiologic agent was identified by cultural methods as *Escherichia coli* communis. Immediate surgical exploration of the healed bullet wound was done, although there was no evidence of local infection. A large subdural abscess was evacuated and a bullet measuring 0.6 by 2 cm. was found embedded in the sacrum and protruding into the subarachnoid space.

The bullet was removed, 100,000 units of penicillin powder was sprinkled into the cavity and a small rubber drain was inserted. The immediate postoperative course was characterized by considerable headache, backache and fever. Intensive and prolonged therapy with sulfadiazine, blood transfusions and intramuscular penicillin were given. The latter agent was used only after it was shown that the organism was slightly susceptible to its action.⁴ On the third postoperative day, pro-

Fig. 2.—Location of foreign body.

nounced improvement was evident. Convalescence was satisfactory except for the severe but transitory low back pain and a persistent diplopia. A follow-up made six months after the onset of his illness showed that the patient was perfectly well except for faulty vision in the right eye, photophobia and diplopia. Visual fields were full and normal and fundic examination was negative, but vision in the right eye was only 20/200 uncorrectable. It was believed that the patient had a postencephalitic syndrome secondary to the meningitis with damage to the primary optic centers.

BACTERIOLOGY

The organism cultured from the spinal fluid and the gram negative rod obtained from the abscess in the region of the sacrum gave identical cultural and biochemical reactions. On blood agar incubated for twenty-four hours at 37 C. aerobically, the colonies were large, raised, smooth, opaque, gray and nonhemolytic. The smears showed a short, plump, gram negative rod. They were nonmotile. On an eosin-methylene blue plate the

Fig. 3.—Clinical course and therapy.

colonies were of moderate size and smooth and they possessed a brilliant metallic sheen. There was no growth on Simmons citrate agar. The organism grew on Russell's double sugar slants, producing gas and acid in both slant and butt. The methyl red test was positive. Tests for indole production were positive. There was no liquefaction of gelatin. Milk was turned acid. Acid and gas were produced in glucose, lactose,

3. Stallworthy, K. R.: Meningitis Due to *Bacillus Coli*, *New Zealand M. J.* 42: 165-167 (Aug.) 1943.

4. Gladys L. Hobby (personal communication to the authors) also found that penicillin in large amounts has some effect on many of the gram negative organisms, especially the enteric group.

dulcitol, mannitol and maltose. There was no fermentation of sucrose. These cultural and biochemical reactions are characteristic of *E. coli communis*.

COMMENT

Sulfonamides are frequently used prophylactically in the treatment of battle casualties. Such therapy may serve to mask a persistent infection and later extension may occur without obvious local inflammatory changes. We believe that the course of this patient illustrated such a sequence of events.

There is considerable evidence that sulfonamide drugs are relatively ineffectual in the sterilization of purulent collections. In our case, although there was a definite response to the initial chemotherapy, recovery occurred only after adequate drainage of the focus and removal of the foreign body.

SUMMARY

As a result of a penetrating bullet wound in the region of the second sacral segment, an abscess formed which ruptured into the spinal subarachnoid space and produced an acute purulent meningitis. Intensive chemotherapy brought about temporary improvement, but recovery occurred only after surgical drainage of the abscess.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., *Secretary.*

MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association convened at the Association headquarters on March 9, 1945. Those in attendance were Drs. David P. Barr, S. W. Clausen, Morris Fishbein, E. M. K. Geiling, Robert P. Herwick, James P. Leake, Perrin H. Long, Stuart Mudd, E. M. Nelson, W. W. Palmer, Elmer Sevringhaus, Austin Smith and Torald Sollmann. In addition to members of the headquarters staff there were present Drs. Eben J. Carey, Anthony C. Cipollaro and A. U. Desjardins from the Council on Physical Medicine, Mr. C. S. Ladd from the Council on Foods and Nutrition, Dr. Herman L. Kretschmer, President of the American Medical Association, Dr. J. J. Moore, treasurer of the Association, Dr. Ernest E. Irons, Secretary of the Board of Trustees, and Dr. Stanley Weld, Dr. E. M. Shanklin, Dr. L. Fernald Foster and Dr. John S. Bouslog from the Advisory Committee of the Cooperative Medical Advertising Bureau.

The following is an abstracted report of some of the more important discussions and actions:

Food and Drug Requirements for Adequate Directions on Label.—Some regulations provided by the recent amendments of the Food, Drug and Cosmetic Act were reviewed. It was apparent that the Food and Drug Administration is pursuing objectives held desirable by the Council, and no formal action was taken.

Promiscuous Use of Vitamins.—Discussion was given to recent experimental work which suggests that it is possible to give excessive doses of vitamins, particularly members of the B complex, in the presence of certain infections. In experimental animals it has been possible to increase the probability of developing paralysis and a fatal outcome in anterior poliomyelitis by increasing the intake of thiamine hydrochloride. Warnings have been offered that a number of virus infections have been made worse even by adequate, certainly by excessive, vitamin intake. Further, there is some evidence that there may be an antagonism between administration of members of the B complex and certain therapeutic preparations. Such findings indicate the need for further studies concerning vitamin therapy.

Cosmetic Creams Containing Estrogen.—Further consideration was given to this subject. Since the meeting, a report

on "Status of Cosmetics Containing Hormones" has been published in *THE JOURNAL* (June 16, p. 515).

External Use of Sulfonamides.—The external use of sulfonamide preparations was reviewed, and first hand as well as published information studied. Since the meeting a report on "Dangers from the External Use of Sulfonamides" has been published (*THE JOURNAL*, August 4, p. 1024).

Use of Council Name in Advertising of Nonaccepted Preparations.—Occasionally reference is made to the Council on Pharmacy and Chemistry and to the American Medical Association in such a way as to imply acceptance by or favorable opinion from these bodies when such is not the case. It was moved and adopted that, whenever the name of the Association or the Council is misused in relationship to the promotion of new drug products, the Secretary be automatically authorized to write requesting the discontinuance of such use.

A. M. A. Cooperative Medical Advertising Bureau.—Discussion was held with members of the Advisory Committee of the Cooperative Medical Advertising Bureau, and some of the joint problems were outlined. A committee was appointed to be available for questioning by and to provide assistance to the Cooperative Medical Advertising Bureau.

Radon Ointment.—The status of radon ointments, which are said to be radium emanation (radon gas) incorporated in ointment bases, was reviewed and the subject referred for joint study by the Council on Physical Medicine and the Council on Pharmacy and Chemistry.

Therapeutic Trials Committee.—Further discussion was given to the status of this committee. Since this meeting an informal conference has been held with representatives of industry chosen by the American Drug Manufacturers Association and the American Pharmaceutical Manufacturers Association and a brief account of this conference published (*THE JOURNAL*, July 28, p. 961).

Priority in Research.—The Council had been requested to devise a mechanism whereby individuals can record original contributions in research so that they might support claims for priority. The Council gave the matter careful consideration but considered it inexpedient at this time to undertake such a program.

Globin Insulin.—The status of globin insulin was reviewed, and it was agreed that the statement of actions and uses in N. N. R. should continue to serve as a guide in the preparation of the advertising claims offered for this substance.

Spanish and Other Translations of Council Publications.—This subject was again reviewed, but little progress was reported because of existing difficulties.

The Spread of Infectious Hepatitis by Contaminated Syringes and Needles.—The danger of the spread of infectious hepatitis by contaminated syringes and needles was discussed and a report authorized.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

PENICILLIN (See Supplement, to New and Nonofficial Remedies, 1944, p. 18).

The following dosage form has been accepted:

LAKESIDE LABORATORIES, MILWAUKEE—

Penicillin Sodium: 100,000 Oxford units in 20 cc. vials and 100,000 Oxford units in 20 cc. vials packaged with an accompanying 20 cc. vial of isotonic solution of sodium chloride.

SULFADIAZINE SODIUM (See New and Nonofficial Remedies, 1944, p. 199).

The following additional dosage form has been accepted:

SHARP & DOHME, INC., PHILADELPHIA

Sterile Solution Sodium Sulfadiazine 5% W/V: 50 cc. ampuls. Each 50 cubic centimeters contains sodium sulfadiazine 2.5 Gm. and distilled water q. s.

SATURDAY, SEPTEMBER 15, 1945

THE PRESIDENT OUTLINES A PROGRAM

On September 6 President Harry S. Truman sent to the Congress an outline of the executive and legislative program which he considered desirable. He concluded his presentation:

I shall shortly recommend a national health program to provide adequate medical care for all Americans and to protect them from financial loss and hardships resulting from illness and accident. I shall also communicate with the Congress with respect to expanding our social security system and improving our program of education for our citizens.

In the course of his presentation the President referred to several projects of specific interest to the public health. Many of the war agencies are carrying on functions related to medicine and the public health. The President urged that the Congress not yet adopt a resolution proclaiming a termination of the war or the termination of the emergency or the cessation of hostilities, since such a resolution would automatically cause the death of many war powers and wartime agencies before we are ready. Obviously the physicians, the medical students and the premedical students now held by the legislation declaring a war emergency would be released from such service within six months of the time of the declaration of the end of the emergency. In the absence of such a declaration the existing war agencies, including particularly the medical departments of the Army and Navy and the United States Public Health Service, should do their utmost to obtain the release of as many of these personnel as possible at the earliest possible moment in order to meet a gradually developing emergency in the provision of medical service to the American people.

The President has urged, as has already been noted, extension of the Selective Service to permit the induction of men between the ages of 18 and 25 for a maximum service of two years. Unless some provision is made for filling our universities and colleges with men in the premedical, preengineering, pre dental, prepharmaceutical and similar courses, our country will find itself in a grievous situation for the training of scientists even before 1948.

The President urged on the Congress the early adoption of legislation for the establishment of a single federal research agency. He recognized that science cannot be dictated to or regimented. During the time necessary to organize a national research agency, he requested the Office of Scientific Research and Development and the Research Board for National Security to continue their work.

The confusion that prevails in the disposal of surplus property is more than even the most radical of newspapers has been able to reflect. Physicians are coming out of the service who desire to avail themselves of surplus property in order to reestablish themselves in medical practice. Hospitals, which have deteriorated in the quality of their service during the war because of inability to obtain new equipment, are anxious to obtain such surplus property at the earliest possible moment. The President admitted the confusion that prevails and urged the appointment of a single administrator, who may be able to bring some order out of the chaos and hasten the disposal of the billions of dollars of surplus property, much of which is related to the maintenance of health and the care of the sick.

Reform of the medical care now available in the Veterans Administration has been repeatedly indicated by a series of articles in lay and medical periodicals. The President recommended that the Congress give prompt consideration to the recommendations which had been made by the Veterans Administration for the purpose of clarifying and liberalizing the provisions relative to hospital and medical care. In a recent report Mr. Bernard Baruch suggested that the administration and delivery of medical service to veterans be completely separated from those functions that concern compensation, pensions and insurance provisions. This would seem to be well nigh a necessity as the first step in improving the quality of medical service given to the veterans.

As postwar construction projects, the President mentioned particularly the necessity for hospitals and health centers. Thus he said:

The Congress has also been giving consideration to legislation with respect to the construction of hospitals and health centers throughout the country. . . . The federal government must continue to recognize its obligation to maintain and improve the health of the nation by providing federal grants where necessary for the construction of hospital and health centers.

These citations are but a meager indication of the innumerable problems related to the health and medical care of the people of the United States that will concern the Congress at this session. The medical profession must be alert to the legislative proposals that will be developed by the Congress in response to the suggestions of the President. Translation of these suggestions into legislation may introduce innumerable features of fundamental importance to the future of the practice of medicine in our country.

VIRUS MYOCARDITIS

A filter-passing agent that produces lethal myocarditis in anthropoid apes, mice, guinea pigs and rabbits has been described by Helwig and Schmidt¹ of the A. A. F. Regional and Convalescent Hospital, Miami Beach, Fla. In November 1944 the body of a well nourished adult male gibbon was brought to their laboratory. The animal had always been well, until one morning it suddenly dropped dead without previous indication of illness. The animal had not shown paralysis. Necropsy revealed a dilated heart, pericardial effusion, pulmonary edema and a bilateral hydrothorax. Microscopic examination showed an intense diffuse myocarditis and pulmonary edema, the remaining viscera being normal. Six weeks later a 5 year old well nourished male chimpanzee from the local Anthropoid Ape Research Foundation also died suddenly. The previous history also had been negative, and the same gross and microscopic findings were recorded as with the gibbon.

Fluid from the chest cavity of this chimpanzee was inoculated intravenously, intracranially or intraperitoneally into a series of mice. The mice developed paralysis by the fifth day and were all dead by the sixth day. On microscopic examination all showed acute myocarditis. As a control, chest fluids from 2 chimpanzees dying from other causes were similarly inoculated into mice, none of which developed symptoms or showed lesions of the myocardium when later killed.

The hearts from the first series of injected mice were ground in ascitic fluid and used for intravenous and intraperitoneal inoculation into a second series of mice. Half of the second series developed lethal myocarditis. Heart suspensions from the lethal cases were similarly injected into a third series of mice, all of which developed lethal myocarditis. By this technic the causative agent has been propagated through the fifth mouse passage with continual increase in mouse pathogenicity. The causative agent will pass through a Seitz or Berkefeld filter and will also produce interstitial myocarditis in guinea pigs and rabbits. Guinea pigs and rabbits, however, usually do not show an accompanying paralysis.

The virus is present in infective concentration in the nasal washings of inoculated mice. Mice may be readily inoculated by intranasal instillation. The agent is readily cultivated in embryonated hen's eggs and will stand heating to 56 C. for twenty minutes. It is completely destroyed, however, by heating to 70 C. for a similar time.

Demonstration of the viral etiology of anthropoid myocarditis is clinically interesting, since cases of this disease are strikingly similar to those of sporadic cases of human acute interstitial myocarditis of unknown

etiology. As far as known, the anthropoid myocarditis virus has not been previously described. The nearest approach to this virus is apparently the rheumatic endocarditis virus recently described by MacNeal and his associates² of the New York Post-Graduate Medical School. Therapeutic and electrocardiographic studies of experimental viral myocarditis of rabbits and guinea pigs are now in progress in the Miami Beach Laboratory.

EARLY OUTBREAKS OF INFANTILE PARALYSIS

In 1843 George Colmer¹ reported the occurrence in the fall of 1841 of some 10 cases of paralysis in teething children in the parish of West Felecia, La. This report has been regarded as the first record of an epidemic of infantile paralysis. Apparently, a few years earlier, in 1836, Sir Charles Bell, the celebrated anatomist and experimenter, inserted in one of his case reports² the following note about an epidemic fever with wasting of limbs among children on the island of St. Helena:

A lady, whose husband was the English clergyman at St. Helena, consulted me about her child, who had one leg much wasted in its growth. In conversing about the illness which preceded this affection in her little girl, she mentioned that an epidemic fever spread among all the children in the island about three or five years of age; and her child was ill of the same fever. It was afterwards discovered that all the children who had the fever, were similarly affected with a want of growth in some part of their body or limbs! This deserves to be inquired into.

So far, no further reference to the St. Helena epidemic has been found in the writings on infantile paralysis.

Beginning in the early part of the last century the clinical reports of cases of infantile paralysis, singly and in small groups, steadily increased in the English, German and French literature. In Norway cases were observed as far back as 1820. In the first reports by orthopedic surgeons on clubfoot mention is commonly made of paralysis in childhood following acute illness. Monteggia³ in 1813 described the disease in Italy. By 1850 it had become fairly well known that adults are not exempt. Two other early outbreaks may be mentioned: Black⁴ observed 6 nonfatal cases in children from 1 to 8 years of age in Cambridge, Ohio, in the summer and autumn of 1858. Cambridge then had a population of about 1,500. Black states definitely that he did not see any other cases later. The cases he observed are well described. He speaks of the dis-

ease as "a somewhat rare affection, infantile paralysis." In 1863 Bull⁵ in Norway reported to the health authorities 14 cases with three deaths, which first were regarded as cases of meningitis but subsequently found to be cases of typical infantile paralysis.

The virus of infantile paralysis was widely disseminated long before the advent of the large epidemics which have been occurring since about 1885; the small outbreaks recorded by Bell, Colmer and others may be regarded as forerunners of the widespread, serious epidemics that confront the world today.

THE DISCHARGE OF MEDICAL OFFICERS

From the Office of the Surgeon General comes official announcement that some 13,000 to 15,000 medical officers will be discharged by the Army before Jan. 1, 1946. At present every possible effort is being made to rotate the men now in the service in order to return men now overseas as soon as possible. Authorities also want to give opportunity for practice in their specialties and for education in specialties to men who have had service thus far primarily as battalion surgeons.

Almost daily THE JOURNAL receives letters from physicians in the service who complain of wrong assignment, of failure to be promoted, of lack of sufficient duties to keep them fully occupied or for a variety of other causes. Regularly these statements have been sent, in the vast majority of instances without the name of the physician who wrote, directly to the Office of the Surgeon General, and every effort has been made to secure adjustment.

Beginning with next week THE JOURNAL will publish the names of medical officers discharged from the service as rapidly as they can be supplied by the Offices of the Surgeon General and the Adjutant General of the Army. Already there is a backlog of some several thousands of names of men who have been discharged for various reasons beginning almost with the date of the attack on Pearl Harbor. This published list will be arranged alphabetically by states and will include the name of the officer, the rank in the service and the place at which he was inducted into the armed forces.

Through the Bureau of Information of the American Medical Association medical officers are being supplied at the time of discharge with information regarding licensure and reciprocity in the various states, the names of responsible officials, the facts regarding facilities for practice, and the numbers of physicians in various counties as well as other information which is gradually being developed through this bureau. The Bureau of Information of the Association was established not only to aid the returning medical officer in relocation but also to encourage redistribution of physicians in order

to meet the needs of communities that are without sufficient medical personnel. The Bureau will attempt to supply returning medical officers with information and advice. Requests from medical officers are welcome.

Current Comment

THE HERSHEY CONFERENCE ON PSYCHIATRIC REHABILITATION

The Hershey (Pa.) conference (Feb. 1, 2 and 3, 1945) was planned to discover ways of increasing the resources of psychiatry and general medicine to meet the needs of men returning from the armed services with neuropsychiatric disabilities other than psychosis.¹ It was estimated that the number of men with such conditions may be considerably over 2,000,000: some 1,500,000 neuropsychiatric rejectees, 600,000 neuropsychiatric dischargees and 200,000 not so labeled but in whom a neurotic illness underlies or seriously complicates organic illness. The conclusion reached by the conference was that the recognized need for professional help in overcoming psychiatric handicaps is already too great to be met with the resources at hand and will increase sharply with general demobilization, with the stress of adjustment to civilian life and especially with deterioration of employment opportunities. The conference has recommended several measures, among them that the psychiatric training of picked medical personnel in military installations be continued and expanded. Facilities other than hospital care for the treatment of men with psychoneurotic reactions should be further developed in military installations in the hope that many more men can be retained in service for treatment which is not at present available in civilian life. The committee also recommended that the National Committee for Mental Hygiene should intensify its efforts to arouse and inform the public, and in particular the church, the schools, industrial management and labor, as to the needs and care of veterans with psychoneurotic reactions and to promote the training and efficient use of psychiatric social workers. Physicians engaged in the practice of general medicine need education on the neuroses and their care. For the graduate training of internists and general medical men already introduced to, or interested in, psychiatric aspects of medicine as a result of their war experience, fellowships should be made available, and these stipends should be large enough to attract men already well equipped professionally and with family responsibilities. Graduate training for comprehensive medical care would be facilitated if the American Boards of Internal Medicine and Pediatrics credited to a limited extent appropriate experience in psychiatry and if the American Board of Psychiatry and Neurology reciprocally credited appropriate experience in internal medicine or pediatrics. Training for the specialty of psychiatry should give increasing attention to the treatment of the psychoneuroses as they present themselves in both psychiatric and general medical practice.

MEDICINE AND THE WAR

NAVY

HEALTH CONDITIONS IN THE NAVY

Statement by Vice Admiral Ross T. McIntire
(MC), U.S.N., Surgeon General

HOSPITAL FACILITIES

Despite the surrender of Japan, the number of patients in naval hospitals within the continental limits will increase during the next few months. This is the logical result of the steady evacuation to the United States from Pacific areas of hospitalized personnel.

Although the normal capacity of statewide naval hospitals is 72,531 at present, the use of double-deck beds and adoption of other emergency measures has sent the actual capacity beyond the 100,000 mark. For the week ended August 15 the patient census was 89,798.

Today there are in operation, within the continental United States, fifty-four naval hospitals. Forty are general hospitals, thirteen are for convalescent care and one serves chiefly as a distribution hospital. With the possible exception of the last named institution, it does not appear that any of these fifty-four can be released for at least eight more months. When the time comes, our so-called special, or convalescent, hospitals will be the first to be relinquished, since all thirteen are housed in privately owned buildings which were volunteered to the Navy.

A new naval hospital at Houston, Texas, of permanent construction is scheduled to go into commission the first of next year. It will accommodate 1,000 patients.

Plans are well under way to establish a 1,500 bed hospital at Camp Wallace, Texas, utilizing facilities which have been turned over by the Army. These include a dispensary of 350 beds and several barracks buildings. Another army transfer is Camp White, in Oregon, which is due to be established within the next week with 1,500 beds. Still another transfer is Camp Phillips, Kansas, which we expect to get from the Veterans Administration and transform into a 1,500 bed naval hospital.

The Veterans Administration, on the other hand, will receive from the Navy three hospitals as soon as they can be released. They are the 1,000 bed facility at Dublin, Ga., which was commissioned last March, and two smaller ones in Texas which have not yet been constructed, one at Austin, which will be of permanent construction and have a normal capacity of 500 beds, and the other at Marlin, to consist of both permanent and temporary construction and have a capacity of 500.

Other postwar hospital plans, subject to change, call for:

A 500 bed hospital at Beaufort, S. C., to replace the outdated U. S. naval hospital at Parris Island, S. C., which is of World War I vintage.

A 1,000 bed hospital at St. Alban's, L. I., N. Y., to serve as the main institution of its kind in the Third Naval District, taking the place of Brooklyn Naval Hospital.

Another new plant of the same size to fulfil the same purpose for the San Francisco Bay area.

Investigation of the need for establishing, probably in the central part of the country, a naval hospital for psychotic (insane) patients, having a capacity of 1,500 patients.

Study of the need for a permanent tuberculosis treatment center on the East Coast. Pulmonary cases, at present, are sent to the U. S. Naval Hospital, Sampson, N. Y., which is an emergency wartime facility of temporary construction.

EVACUATION OF NAVAL PATIENTS

Reports to the Bureau of Medicine and Surgery indicate that nearly 15,000 naval patients, including Marines, remain to be returned to this country from Pacific areas. Most of these are in Hawaii and the Marianas. They are distributed among twenty hospitals, with a relatively small number in transit aboard naval hospital ships.

Approximately 1,800 are being returned to the mainland weekly by surface ship and plane. At this rate the evacuation task should be completed by mid-October. This does not mean that it will then be possible to roll up our overseas hospitals. Many eventually will be disestablished, but others will have to be retained indefinitely to serve the continuing needs of the Navy. In fact, seven more are now in process of being set up: four fleet hospitals and one base hospital on Okinawa and two base hospitals in the Marshalls.

SPECIAL TREATMENT CENTERS

A sizable proportion of naval patients, particularly those suffering combat wounds, are under treatment at the special centers that have been created at certain of the naval hospitals.

During the week ended August 22, 937 amputees were in the wards of Philadelphia and Mare Island naval hospitals. For the same period Philadelphia had 47 blind patients and 483 deaf patients under treatment and rehabilitation. A total of 796 plastic surgery patients were in the wards at Bethesda, Md., Oakland, Calif., St. Alban's, N. Y., and San Diego, Calif. In the neurosurgery centers at the same four hospitals 1,331 patients were aboard.

Tuberculous patients under treatment at Corona, Calif., for the same week totaled 954, and there were 603 at Sampson, N. Y. Corona, along with Dublin and Palm Beach, also is a treatment center for rheumatic fever.

Since Pearl Harbor, amputation cases have totaled approximately 2,300, blindness 190 and deafness 3,100.

HEALTH OF THE NAVY

As the result of a combination of many factors, not the least of which was Providence, the Navy has come through in splendid shape with regard to conservation of manpower and the saving of life. The fact that 97 out of every 100 men wounded survived may be attributed to the adequate provision of whole blood and the shock preventing blood derivatives; to swift and efficient evacuation, most dramatically by air, to rear hospitals; to the high standards of personnel and equipment possessed by these hospitals; to the gains in knowledge that were made both in the prevention and in the treatment of wounds, injuries and disease; and, finally but far from least, to the skill and labor of our doctors, nurses and hospital corpsmen.

At home there was not a single epidemic of major proportions among naval personnel. Overseas the early problems of malaria and filariasis responded swiftly to rigid sanitary measures. With respect to these two infections, it is significant that the U. S. Marine Barracks at Klamath, Ore., a special activity established last year to recondition an alarmingly large number of Marines who fell prey, is now being utilized as an ordinary convalescent, or retraining, center because the problem which it was set up to combat is virtually solved.

Number One cause for admission to Navy sick lists, as well as for medical discharge, is mental disease. This includes not only the psychoses but the various psychoneuroses and lesser conditions which are completely curable in most instances. During the war years, from January 1942 through June of this year, 25.8 per cent of all naval medical discharges were neuropsychiatric cases. For the first half of 1945 the figure was 31 per cent. In 1944 mental diagnoses accounted for a number of cases which was only 1.4 per cent of total naval strength. In 1944 also the rate of neuropsychiatric admissions ascribed to naval service was one-half that in the existed prior to enlistment category. Another heartening development was that neuropsychiatric discharges for the first half of this year showed a 2 per cent decrease compared with 1944. Sixty-five per cent of naval psychotic patients made recoveries to the point where they may be discharged from hospitals in three months, an additional 15 per cent in the next three months.

NAVY TO RETURN V-12 STUDENTS TO INACTIVE DUTY

Approximately 8,500 students in the Navy V-12 Program pursuing medical, dental, theological, premedical, predental and pretheological training will start returning to inactive duty on November 1. The remaining 25,500 students in the Navy V-12 Program will either graduate or continue their training in college as apprentice seamen on active duty. Final disposition of all students in the program will be made by June 1946.

As previously announced, V-12 training at 69 of the 124 colleges and universities throughout the country with V-12 and NROTC units will terminate on November 1. Training will continue at 42 NROTC units and 13 V-12 units in the program and at 10 newly established NROTC units.

Approximately 5,700 medical and 1,450 dental students will remain on active duty until the end of the semester now current or starting before November 1. Another 1,500 V-12 students entering medical or dental school this fall will remain on active duty for one term. Medical and dental students will be returned to inactive duty as enlisted men and will subsequently receive probationary commissions in the Naval Reserve and be retained on inactive duty.

A total of 250 theological and 95 pretheological students will return to inactive duty as enlisted men at the end of the academic term now current or starting before November 1. Later those eligible will receive probationary commissions as ensigns in the Naval Reserve and be retained on inactive duty.

There are 1,056 premedical and predental students in the program who will return to inactive duty as apprentice seamen at the end of the current academic term on November 1.

V-12 trainees now enrolled in the NROTC or who are scheduled to be so enrolled on or before November 1 will be retained under instruction on active duty until June 1946 unless they become eligible for commissions or discharge from the service at an earlier date. Students specializing in engineering will continue their training after November 1 in the Navy V-12 Program as scheduled. Marine Corps students in the V-12 Program will continue their training after November 1.

Students in the Naval Aviation Preparatory Program who are either in college training now or who are scheduled to enter the program on or before November 1 will be retained under instruction on active duty.

MEDICAL STATISTICS DIVISION

In line with the reorganization of various divisions of the Bureau of Medicine and Surgery, a Medical Statistics Division has been established which requires the transfer to it of functions and personnel from the former Medical Statistics Branch of the Preventive Medicine Division.

The new division consists of (a) an Office of the Chief of Division, (b) a Statistical Planning and Analysis Branch, (c) a Statistical Processing Branch and (d) a Statistical Publications Branch. The chief of the division will be responsible to the chief of the bureau for the performance of all functions assigned to the Medical Statistics Division.

The Statistical Planning and Analysis Branch will determine medical statistical needs, carry out statistical projects, prepare statistical reports and publications, provide a statistical consulting service and maintain liaison with other military and civilian agencies.

The functions of the Statistical Processing Branch will be to collect, process, compile and tabulate medical statistics from naval activities and, where necessary, from other military and civilian agencies. To carry out these functions the branch will consist of (a) an Editing and Coding Section, (b) a Machine Processing Section, (c) an Annual Report Section, (d) a Monthly Report Section and (e) a Miscellaneous Reports Section.

The Statistical Publications Branch shall prepare, edit and review statistical reports and publications and shall consist of (a) an Editorial Section, (b) a Drafting Section and (c) a Copy Preparation Section.

NAVY AWARDS AND COMMENDATIONS

Commander Richard S. Silvis

The Silver Star Medal was recently presented to Comdr. Richard S. Silvis, formerly of Washington, D. C. The citation accompanying the award read "For conspicuous gallantry and intrepidity in action against the enemy Japanese forces while serving as surgeon of a Marine division on Iwo Jima, Volcano Islands, from Feb. 19 to March 16, 1945. At 2:20 on the morning of March 7, owing to an unforeseen number of incoming casualties urgently requiring whole blood, the supply at the division field hospital became depleted. Commander Silvis personally undertook the vital task of obtaining an additional supply. Just at this critical time an air raid alarm was sounded and all ships in the harbor started making smoke, reducing the visibility to zero. In coordination with the air raid alarm, the Japanese began dropping mortar shells. Because of the impenetrable smoke and darkness the road was indiscernible, but Commander Silvis, with utter disregard for his personal safety, walked in front of the vehicle, feeling his way by the ruts, guiding the driver by verbal commands. Arriving at his destination he obtained the vitally needed whole blood and retraced his steps through the darkness; the blood was immediately used, thereby saving many lives. His heroic conduct was in keeping with the highest traditions of the United States Naval Service." Dr. Silvis graduated from the University of Nebraska College of Medicine in 1931 and entered the service June 26, 1931.

Captain Charles P. Archambeault

A Gold Star in lieu of a second Bronze Star medal was recently presented to Capt. Charles P. Archambeault, formerly of Washington, D. C. The citation accompanying the award read "For meritorious achievement in connection with operations against the enemy while serving as surgeon for a Marine division during the planning, training and assault phases of the campaign for Iwo Jima, Volcano Islands, from Oct. 31, 1944 to March 16, 1945. During the planning and training phases of the operation Captain Archambeault's careful supervision, high ability and unceasing efforts were in great degree responsible for the unsurpassed health of the division's troops and for the timely and efficient preparations made to insure their continued health during the campaign. Landing on Iwo Jima under heavy fire and making frequent trips to the most forward aid stations, he unhesitatingly and without pause gave himself to the task of providing the best medical care for the wounded and for protecting the health of the troops. His efficient, wise and forceful leadership produced an outstanding record of medical care for the men and was instrumental in the magnificent success of the operation. His conduct throughout was in keeping with the highest traditions of the United States Naval Service." Dr. Archambeault graduated from Albany (N. Y.) Medical College in 1918 and entered the service Nov. 12, 1920.

Lieutenant Richard H. Wilcox

Lieut. Richard H. Wilcox, formerly of Pendleton, Ore., was recently awarded the Bronze Star. Commanding a medical company attached to the Marine 5th Amphibious Corps on Iwo Jima "he demonstrated exceptional qualities of leadership and resourcefulness in overcoming the difficulties of terrain and harassing enemy artillery fire to establish his medical company for the reception and treatment of battle casualties within a period of twenty-four hours." Dr. Wilcox graduated from the University of Louisville School of Medicine in 1934 and entered the service Oct. 19, 1942.

Lieutenant Commander Daniel Rakov

The Legion of Merit was recently presented to Lieut. Comdr. Daniel Rakov, formerly of Maybrook, N. Y. The award was given for his service, beyond the call of duty, while serving as medical officer on the U. S. S. *Suwannee*, Oct. 25-28, 1944, during the invasion of Leyte. Dr. Rakov graduated from Syracuse University College of Medicine in 1922 and entered the service Feb. 22, 1943.

ARMY

PROFESSIONAL TRAINING OF REGULAR ARMY
MEDICAL CORPS OFFICERS

During the period of the emergency it has been necessary to place the bulk of Regular Army Medical Corps officers in administrative positions in the major commands of the Army. This necessary procedure has caused a shortage of adequately, professionally trained Regular Army Medical Corps officers to take up the care of the Army sick and wounded on the release of A. U. S. officers to civilian life.

In order that the Medical Department may be prepared to continue the excellent professional care of the sick and wounded in army hospitals, the Surgeon General has requested the chief of staff to authorize courses in professional training for Regular Army Medical Corps officers. This request has been approved, and a plan of training officers being relieved from administrative or other assignments where professional experience was not available has been developed and placed in operation. This plan calls for the assignment of Regular Army Medical Corps officers to installations where courses in professional training, eventually leading to board certification, is to be carried out. This plan calls for training, not only in military medical installations, but in leading civilian installations. Representatives of all major forces concerned have contributed to this plan, and officers assigned to any of these forces are eligible for the professional training.

This plan has been put into immediate operation in order that fully qualified Regular Army Medical Corps officers may be available to replace the presently highly qualified A. U. S. officers who are to be released in the present demobilization program and who are at present holding the top professional positions in army hospitals.

The Surgeon General is insistent that the noteworthy record of care of the sick and wounded in this war be maintained, and for this reason the far reaching plan which he has prepared places foremost the professional qualifications and continued professional training of the Medical Corps officers. It is the sincere hope of the Surgeon General that all Medical Corps officers of the Army of the United States give earnest consideration to a career in the Regular Army, and he feels that with the development of his present plan excellent opportunity for professional advancement will be afforded to all Medical Corps officers.

CAPTAIN HELEN W. BRAMMER
AWARDED BRONZE STAR

Capt. Helen W. Brammer, formerly of St. Ansgar, Iowa, was recently awarded the Bronze Star for meritorious achievements in connection with military operations in North Africa and Italy. Describing her accomplishments from February 1943 to July 1944 the citation pointed out that, "as chief nurse, Captain Brammer regardless of personal sacrifice organized and administered without adequate assistance the nursing services necessary to operate the hospital. With patience, resourcefulness and leadership she aided members of the nursing service in the proper handling and care of the sick and wounded. During periods when her hospital was treating patients far in excess of its normal capacity she contributed materially to the success of the station hospital in rendering the highest possible medical services to the armed forces of the United States." Formerly with the University of Iowa School of Medical and Surgical Supervision, Captain Brammer has been overseas since Jan. 14, 1943.

WOUNDED KEEP TRACK OF OLD UNITS
THROUGH "OUTFIT" MAGAZINE

Wounded personnel of the Army in hospitals throughout the United States are keeping track of their old outfits and comrades through the medium of *Outfit Magazine*, a publication of the Information and Education Division, Army Service Forces. The magazine is published weekly by the New York Branch, Information and Education Division, and consists of sixteen pages of news and pictures about army units at present over-

seas. It has provided a link between the hospitalized casualty and his original unit.

The first issue of *Outfit Magazine* was distributed in United States hospitals in November 1944. Since then the magazine has established bureaus consisting of one officer and enlisted assistants in every overseas theater. Each issue is distributed free to wounded veterans and consists of news material, grouped by theaters, of units ranging from divisions down to companies.

106TH STATION HOSPITAL AWARDED
UNIT PLAQUE

The 106th Station Hospital, a unit of the Peninsular Base Section, was recently awarded the Meritorious Service Unit Plaque "for superior performance of exceptionally difficult tasks and outstanding devotion to duty." Col. Charles F. Fisher, formerly of Clarksburg, W. Va., is commanding officer of the 106th Station Hospital.

ARMY AWARDS AND COMMENDATIONS

Major General George C. Dunham

The Distinguished Service Medal was recently awarded to Major Gen. George C. Dunham of Washington, D. C. The award was conferred on General Dunham by the Surgeon General of the Army, Major Gen. Norman T. Kirk. The citation, stressed the fact that General Dunham—called in an American Hospital citation the 'World's Greatest Bug Hunter'—has personally directed the Inter-American war against disease.

"Spending much of his time supervising field workers he directed the establishment of hundreds of health centers, clinics and medical posts which provide preventive and therapeutic services. Through General Dunham's performances in discharging duties of great responsibility, large populations in other Americas have benefited from expanded health and sanitation facilities. Standards have been raised and important forward steps have been taken in cooperative effort toward the economic development of the hemisphere."

The citation also recalled that it was General Dunham who "originated and developed a broad principle which was applicable to republics with differing problems, sources and governmental structures." It gave him full credit for negotiating basic agreement for the Institute of Inter-American Affairs, an agency of the Office of Inter-American Affairs, which brought about "a comprehensive public health program in the other American republics."

General Dunham graduated from the University of Oregon Medical School, Portland, in 1914, entered the Army Medical Corps in 1916 and graduated from the Army Medical School in 1917.

Colonel Achilles L. Tynes

The Legion of Merit was recently awarded to Col. Achilles L. Tynes, Washington, D. C. According to the citation "As Chief of the Hospital Construction Branch, Hospital Division, Office of the Surgeon General, from September 1943 to February 1945 he displayed unusual foresight and excellent judgment in supervising the development and application of planning standards for the entire fleet of twenty-nine Army hospital ships and for hospital facilities on troop ships. His skillful work was a major factor in expediting the conversion of many merchant ships to this important war service, making it possible to provide high standard medical care near forward combat areas. At the same time he guided the planning, building requirements and construction standards of the hospital system within the continental United States during a period of tremendous expansion. He rendered services that contributed materially to the efficiency of the Army's medical service." Dr. Tynes graduated from the University of Virginia Department of Medicine, Charlottesville, in 1930 and entered the service June 16, 1930.

Major Douglas P. Head

Major Douglas P. Head, formerly of Minneapolis, was recently awarded the Bronze Star for his research in connection with the detection and treatment of peptic ulcers in the Mediterranean theater. Describing Major Head's meritorious achievements in North Africa and Italy from May 15, 1943 until cessation of hostilities there, the official citation stated that "during this period Major Head contributed in large measure to the development of policies to govern the detection, diagnosis, treatment and disposition of peptic ulcer in the Mediterranean Theater of Operations. As a result of his work the theater's handling of such cases was commended by the civilian consultant to the Secretary of War. In addition, as co-author of a monograph on theater experience with the disease Major Head contributed to an outstanding compilation of facts which was a model on which policies in respect to peptic ulcer in the armed forces of the United States were based." Dr. Head graduated from the University of Minnesota Medical School, Minneapolis, in 1927 and entered the service Feb. 16, 1942.

Colonel Wilford F. Hall

The Legion of Merit was recently awarded to Col. Wilford F. Hall, formerly of Bridgeport, Conn., for "service as chief of the Personnel Division, Office of the Air Surgeon, from February 1942 to February 1943. Following the declaration of war it immediately became apparent to him that the AAF would undergo an expansion beyond any peacetime perception. Aware of the urgent problem of staffing the many newly activated stations with medical officers, this officer conceived and developed a procedure by which physicians were solicited, physically examined and appointed in the Army of the United States for duty with the AAF. Through his efforts, initiative and devotion to duty he secured for the AAF the finest profession-

ally qualified medical corps officers available and properly assigned these officers to stations where they could best serve the AAF and the war effort. The accomplishment of this tremendous and outstanding task contributed materially to the effective realization of the AAF mission." Dr. Hall graduated from Washington University School of Medicine in 1928 and entered the service Aug. 1, 1929.

Major Clyde J. Rademacher

Major Clyde J. Rademacher, formerly of Bend, Ore., was recently awarded the Bronze Star for his work with the First Army headquarters during the Normandy landings. Dr. Rademacher graduated from the University of Minnesota Medical School, Minneapolis, in 1930 and entered the service April 12, 1941.

Colonel Francis J. McGowan

The Air Medal was recently presented to Col. Francis J. McGowan, formerly of New York, "for participation in aerial flights over enemy territory, which included making numerous landings on air strips near enemy bases." Dr. McGowan graduated from Columbia University College of Physicians and Surgeons, New York, in 1921 and entered the service Oct. 2, 1942. He was previously awarded the Bronze Star and Oak Leaf Cluster (THE JOURNAL, May 19, 1945, p. 210).

Major James W. Brooke

The Soldier's Medal with Oak Leaf Cluster and the Air Medal were recently awarded to Major James W. Brooke, formerly of Madison, Wis., during his service with the 8th Air Force. Dr. Brooke graduated from the University of Oregon Medical School in 1938 and entered the service June 2, 1941.

MISCELLANEOUS**BRITISH AND FRENCH OFFER
GRADUATE COURSES**

In the first three months of a program of medical and surgical retraining for civilian practice, more than 300 army medical officers have attended six of the leading medical schools in England and France since June. In addition many officers have been placed by the Information and Education Division in Europe and the Office of the Chief Surgeon in numerous hospitals and clinics to observe British and French methods.

One of the English schools selected by the Office of the Chief Surgeon for a continuous program of observation and study is the British Post-Graduate Medical School of the University of London. At the Post-Graduate School medical officers take a six week course in which they attend classes conducted by leading physicians and surgeons of England, make ward rounds as observers and observe in the clinics and operating theater.

At the Hammersmith Hospital, which is cooperating with the University of London, classes are held by the Post-Graduate School in pathology, in general surgery and in obstetrics and gynecology. Two other hospitals in London are used by medical officers taking classes at the school, although they are not regularly used by the University of London. These hospitals are the Chelsea Hospital for Women and Queen Charlotte's Maternity Hospital.

There are courses in neurology at the National Hospital for Nervous Diseases, London, in psychiatry at the York Clinic of Guy's Hospital, London, and at the Sutton Emergency Hospital, Sutton, Surrey, and in orthopedics at Queen Mary's Hospital, London.

Courses are being conducted at Oxford University, the Royal Army Medical College and Liverpool University Medical School, while other courses will be offered at other times in additional schools.

In France the Information and Education Division placed thirty-five medical officers with the Faculté de médecine of the University of Paris as observers in clinical research, diagnosis and surgery in eight hospitals in the Paris area. Hospitals and surgery in eight hospitals in the Paris area. Hospitals and surgery in eight hospitals in the Paris area. Hospitals and surgery in eight hospitals in the Paris area.

and obstetrics are the Clinique Baudeloque, Hôpital Broca, Hôpital de la Pitié, Asile Sainte-Anne, Hospice de la Salpêtrière, Clinique Tarnier, Hôpital de Vaugirard and La Maternité.

**MEDICAL STUDENTS TO BE DEFERRED
BY DRAFT BOARDS**

A memorandum issued by Lewis B. Hershey, director of the Selective Service System, August 31, makes the following recommendation to local boards relative to deferments of medical students:

3. Special consideration for registrants ages 18 through 25 in certain activities: Local boards will give special consideration to the deferment of registrants for whom there is on file or is hereafter filed a Form 42A (Special—Revised) if they come within one of the groups described as follows:

(a) Students in medicine, dentistry, veterinary medicine or osteopathy: Registrants ages 18 through 25 for whom a Form 42A (Special—Revised) is filed and in whose case the local board determines that they are pursuing a full time course of study in medicine, dentistry, veterinary medicine or osteopathy in a recognized school of medicine, dentistry or veterinary medicine or osteopathy until their graduation, and that they have completed a satisfactory pre-professional course prior to their entrance, will be given special consideration provided that a student of veterinary medicine should not be considered for occupational deferment if he commenced the study of veterinary medicine in a school of veterinary medicine on or after March 15, 1945. A "satisfactory preprofessional course" shall mean such work as is ordinarily required for entrance by medical, dental, veterinary medicine, and osteopathy schools of good reputation.

At the same time the central office of the Procurement and Assignment Service announced the discontinuance as of Sept. 15, 1945 of the plan for certification by state chairmen of registrants aged 18 through 25. Under the present Selective Service policy the deferment of registrants 26 years of age or more will be practically automatic.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Sept. 10, 1945.

Continuance of the Fight Against Venereal Disease and Prostitution

An appeal to communities to maintain wartime gains in the fight against venereal disease and prostitution was made by the Social Protection Division and Public Health Service of the Federal Security Agency, and the American Social Hygiene Association, in cooperation with the Army and Navy. "In 1918 a general relaxing of measures to curtail venereal disease followed the armistice," a statement pointed out. "We must not let history repeat itself. . . . This war against venereal disease is a fight on many fronts. All these sectors—health, law enforcement, ethics, economics and human dignity—are equally important. . . . During the war great gains have been made. These gains must be extended, not lost." District of Columbia Health Department officials are considering means of expanding the venereal disease treatment facilities of the capital, convinced that discharged servicemen, free of restraint, will become "more and more of a problem." Washington authorities are also studying the request of army doctors in Europe that the 1918 rule be imposed preventing diseased soldiers from boarding transports for home. They report a sevenfold increase in the venereal disease rate in the American occupied zone.

Disabled Veterans to Testify on Artificial Limbs

Hearings of the House Committee on Aid to the Physically Handicapped will resume in the Labor Committee room of the House Office Building when disabled war veterans will provide important information designed to aid civilians who have suffered loss of limbs. In addition to the Army and Navy amputees, witnesses will include representatives of the War and Navy departments, Office of Vocational Rehabilitation and other federal agencies and organizations. The committee, headed by Congressman Augustine B. Kelley of Pennsylvania, will study steps being taken to develop more satisfactory artificial appliances and the manner in which civilian amputees are being assisted by federal, state and private agencies. A representative of the Association of Limb Manufacturers of America, Inc., has been invited to the hearings, and there will be spokesmen present for the Veterans Administration, Office of Scientific Research and Development, Disabled American Veterans, American Legion, Veterans of Foreign Wars, American Veterans of World War II and American Federation of Physically Handicapped.

Termination of Federal Nurse Recruiting Program

President Truman has ordered immediate termination of the federal nurse recruiting program. The White House revealed that on September 6 Mr. Truman wrote to Surgeon General Thomas Parran of the U. S. Public Health Service instructing him "to terminate the recruitment of student and graduate nurses immediately and to see to it that no students are enrolled in courses under the nurse training law, which begin after October 15. The end of the war removed the necessity for continuing to start federal training courses for nurses for the armed forces," Mr. Truman said. The White House announcement said the President's action would permit orderly termination of the Cadet Nurse Corps program. It will allow more than 1,100 training schools to adjust their services for peacetime and will enable 30,000 young women enrolled in the Cadet Nurse Corps in current classes to receive federal assistance toward their education.

Extension of Federal Aid to Child Care Centers

Strong support has been given the proposal to extend the Lanham act, with its federal help to child care centers. It has been pointed out that hundreds of thousands of servicemen will not be home for a year or more, and their wives, who must work to support themselves and one or more children, need these centers as much today as before the end of the war. Federal Works Administrator Fleming said he was convinced of the necessity for child care centers in the District of Columbia and in other congested areas. He had ordered the nurseries closed October 31 because "strict interpretation of the law requires it." However, ample funds are on hand to carry the program through the year, he said. Mothers' organizations and newspaper editorials have advocated continuance of the centers.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Message of the President

President Truman transmitted to the Congress, September 6, a message outlining suggested programs to be instituted by the federal government during the postwar period. Among other things he reemphasized the desirability of increased unemployment benefits but cautioned that this recommendation was not to be confused with the broader question of extending, expanding and improving the entire social security program of which unemployment insurance is only a part. He indicated that he would communicate with the Congress at a later date on the need of changes in the social security program. He called attention to the fact that the Congress has been considering legislation with respect to the construction of hospitals and health centers throughout the country and said that the federal government must continue to recognize its obligation to maintain and improve the health of the nation by providing federal grants where necessary for the construction of hospitals and health centers. He devoted a portion of his message to scientific research and urged the early adoption of legislation by the Congress for the establishment of a single federal research agency to promote, among other things, research in the basic and social sciences and in medicine, public health and allied fields. He repeated President Roosevelt's suggestions for an economic bill of rights, which included the right to adequate medical care and the opportunity to achieve and enjoy good health, and indicated that he would from time to time communicate with Congress on "some of the subjects included in this enumeration of economic rights."

Maternal and Child Welfare Act of 1945

Representative Norton, New Jersey, has introduced H. R. 3922, a bill to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children. This is a companion bill to S. 1318, introduced by Senator Pepper and nine other members of the Senate Committee on Education and Labor. The House bill was referred to the House Committee on Labor.

Federal Medical and Nurse Training Schools

Representative Price, Florida, has introduced H. R. 3924, H. R. 3926 and H. R. 3927, proposing, respectively, to provide for the establishment of a United States Naval Medical School, a United States Army Training School for Nurses and a United States Military Medical School. Admission to such schools, it is proposed, will be on the same terms and conditions as admissions to the United States Military Academy or the United

States Naval Academy, as the case may be. On graduation, commissions will be granted as ensigns or second lieutenants, and graduates may be assigned to duty in the Army, the Navy or, in case of nurses, to the Veterans Administration.

Miscellaneous

H. R. 3939, introduced by Representative Stevenson, Wisconsin, proposes an appropriation of \$500,000,000 for expenditure under the direction of the Surgeon General of the United States Public Health Service for research with respect to the cause and cure of cancer and poliomyelitis.

Representative Luce, Connecticut, proposes by H. Con. Res. 71 to record the Congress as believing that every effort should be exerted to give employment to the greatest possible number of veterans of World War II who are physically handicapped as the result of their service in the armed forces.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

The Nebraska Surgical Plan

The Nebraska Surgical Plan, approved by the Nebraska State Medical Association, recently made available to many additional Nebraska communities the system of nonprofit prepayment sickness insurance benefits which already has been in operation in Douglas County since Nov. 1, 1944.

Already 45,984 Nebraskans are receiving the benefits of the Blue Cross plan. The surgical plan in operation in Douglas County in conjunction with Blue Cross has more than 2,000 subscribers.

The surgical plan, which offers subscribers surgical, maternity, x-ray, pathologic and anesthesia benefits, will be integrated with the Blue Cross plan established to subscribers' hospital bills within certain limitations.

Surgical plan subscribers and all their dependents are offered surgical, maternity, x-ray, pathologic and anesthesia benefits. The plan also provides for treatment of certain minor surgical cases in the doctor's office, such as fracture of a wrist, minor lacerations or incision of a boil. It does not cover medical service such as house visits in the case of ordinary illness caused by infectious diseases, influenza, pneumonia or other medical afflictions. When sufficient experience has been accumulated, benefits for treatment of medical cases confined within a hospital will be added to the surgical-maternity benefits.

To insure a fair cross section of subscribers, the surgical plan, like Blue Cross, is offered only on a group basis. In rural areas it is proposed to enroll farm groups through project clubs, townships, school districts and such cooperative groups as the Farmers Union.

The New York Trust Company Provides Hospitalization for Employees

The New York Trust Company has adopted plans to meet the expenses in hospitals of illnesses of employees and their family dependents, it has been announced recently by Mr. John E. Bierwirth, president of the company.

Protection will be provided beginning August 1 through the Blue Cross Plan of Associated Hospital Service of New York and the Doctors' Plan of the United Medical Service, Inc. The company will pay all costs.

In a letter to the employees announcing the adoption of the plans, Mr. Bierwirth explained that provision had been made for the payment of hospital bills and for the cost of medical, surgical and obstetric care in hospitals, and that benefits will be available without waiting periods to all salaried employees who have completed six months or more of continuous service.

This is the third insurance measure adopted by the New York Trust Company for its employees. In 1943 the company established a Retirement Annuity Plan, which was followed in 1944 by an Incentive Compensation Plan for the officers and employees.

Bureau of Information

SUMMARY SHEETS FROM SOUTH DAKOTA AND TENNESSEE

Completed county summary sheets have been received from counties in South Dakota through Dr. Roland G. Mayer, secretary, South Dakota State Medical Association, and from Tennessee through Dr. W. M. Hardy, secretary, Tennessee Medical Association.

The accompanying tables give data from selected counties in these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratios, however, as the future needs of the communities will be largely dependent on younger physicians.

2. Bureau of Census, population 1940.

3. Based on 1940 figures, American Telephone and Telegraph Company.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Medical Needs of Veterans.—A regional meeting on the medical needs of veterans was held at the Veterans Administration Facility, Newington, September 13, under the auspices of the Connecticut State Medical Society and the Veterans Administration. Dr. Joseph H. Howard, Bridgeport, president of the state society, presided, and speakers included Major Gen. Paul R. Hawley, M. C., adviser on medical matters, Veterans Administration, and Capt. Howard H. Montgomery (MC), Washington, D. C.

Research Worker Dies of Poliomyelitis.—A "conscientious objector" working on poliomyelitis as a technician in one of the laboratories at Yale University, New Haven, died of the disease, August 26, according to the Associated Press. The technician, Warren G. Dugan, a graduate of engineering of the University of Illinois, Urbana, was one of three conscientious objectors working in the Yale University School of Medicine and was doing experimental work on infantile paralysis. He became ill on August 24 and died in the New Haven Hospital two days later.

ILLINOIS

Hubert Smith Named Professor of Legal Medicine at Illinois.—Dr. Hubert W. Smith, formerly research associate at the medical and law schools of Harvard University, Boston and Cambridge, has been named professor of legal medicine in the University of Illinois Graduate School. Dr. Smith, who until his recent release from service was acting as legal adviser and officer-in-charge of the legal medicine unit in the Bureau of Medicine and Surgery, U. S. Navy, will in his new appointment carry on research and teaching in the graduate school and teach at the college of medicine in Chicago and probably also in the law school. He will maintain his office on the Urbana-Champaign campus but give about half his time to the Chicago campus. He received his law and medical degrees at Harvard, the latter in 1941. His appointment was made under the new "Distinguished Professorship Fund" of the university, administered by the graduate school.

Chicago

Benefit for La Rabida Sanitarium.—A series of paintings known as the Abbott Collection of Marines in Action, by Kerr Eby, had its first Chicago showing at a benefit preview for the La Rabida Sanitarium September 5. The exhibit was at the galleries of the Associated American Artists under the joint sponsorship of the La Rabida Foundation and the U. S. Marine Corps. The collection was made for Abbott Laboratories and presented to the Navy.

Nonsalaried Faculty Members.—Appointment of 549 doctors to the nonsalaried faculty of the University of Illinois College of Medicine has been announced. This is a reduction of 20 from last year. Of the appointees, 184 are on leave for war service. The nonsalaried faculty of medicine are doctors who give a part of their time to clinical instruction at the university. They receive the benefit of experience with cases brought to the university and its hospitals, at the same time giving the patients and the medical students the benefits of their experience. Appointments are in seventeen departments.

Conference on Tuberculosis.—A conference on control of tuberculosis in a metropolitan area, under the sponsorship of the Institute of Medicine of Chicago, will be held November 13-14 at the Palmer House and will cover phases that are of particular importance at this time to clinicians, specialists, lay workers and teachers, who are cordially invited to attend. There will be panel discussions on financing the tuberculosis problem, the problem of the tuberculous war veteran, immunization with the bacillus Calmette-Guérin, and education of medical students and physicians in tuberculosis. Additional information may be obtained from the Institute of Medicine of Chicago, 86 East Randolph Street, Chicago 1.

Meeting of Statewide Public Health Committee.—On August 29 more than 100 representatives of medicine, education, labor, agriculture, business and other interests participated in the annual meeting of the northern section of the executive board of the Illinois Statewide Public Health Com-

mittee in Chicago. The object of the meeting was to discuss plans for continued efforts to arouse public support for the establishment of county health departments under the 1943 act, a number of which have already been set up through the committee's activities. Benjamin Wham, Chicago attorney and general chairman of the committee, reported that in the two war years following the passage of the act eight counties have adopted health departments, four by resolution of their county boards and four by referendum, and that a large number of counties have local committees actively at work.

Conrad Sommer Goes to St. Louis.—Dr. Conrad S. Sommer recently resigned as deputy director of the mental hygiene service of the Illinois Department of Public Welfare to develop a psychiatric clinic at the St. Louis County Hospital, Clayton, and to accept an appointment as assistant clinical professor of psychiatry at the Washington University School of Medicine, St. Louis. The project at the St. Louis County Hospital, which opened August 1 and which is in charge of Dr. Sommer, serves children and adults through the range of all mental hygiene disorders including behavior problems, neuroses, psychosomatic disorders and psychoses. The clinic's psychotic patients are sent to the Malcolm A. Bliss Psychopathic Institute, St. Louis City Hospital, where the county clinic staff studies the cases in cooperation with the Bliss staff. Patients requiring longer care are sent to the state hospitals at Farmington and Fulton. An attempt is made wherever possible to avoid commitment through the use of community and clinic mental hygiene technics. Dr. Sommer graduated at the University of Illinois College of Medicine in 1932. He had been superintendent of the state division of mental hospitals in Illinois from 1940 until 1943, when he became director of the mental hygiene service.

Symposium on Medicolegal Problems.—The Institute of Medicine of Chicago and the Chicago Bar Association are cooperating in a symposium on medicolegal problems to be held Tuesday evenings, October 9-November 13, at the Chicago Bar Association, 29 South LaSalle Street. Speakers will include:

The Medical Witness in Court: Expert Testimony, October 9—medical discussion: Dr. Oscar Hawkins, chairman, committee on legal problems, Chicago Medical Society; legal discussion: Erwin W. Roemer Esq., member of the Chicago Bar and of the firm of Gardner, Carton & Douglas (the Chicago Medical Society collaborating).

Artificial Insemination: Medicolegal Implications, October 16—medical discussion: Dr. Jacob P. Greenhill, professor of gynecology, Cook County Graduate School of Medicine, attending gynecologist, Michael Reese Hospital; legal discussion: James P. Wright Esq., member of Chicago Bar and of the firm of Rawlins & Wright.

The Practice of Pathology and Its Medicolegal Problems, October 23—medical discussion: Dr. Alan R. Moritz, professor of legal medicine, Harvard Medical School, Boston; legal discussion: Abe R. Peterson Esq., member of the Chicago Bar and of the firm of Eckert & Peterson (the Chicago Pathological Society collaborating).

Operations to Produce Sterility: Medicolegal Implications, October 30—medical discussion: Dr. Frederick H. Falls, head of the department of obstetrics and gynecology, University of Illinois College of Medicine; legal discussion: Burke Shartel Esq., professor of law, University of Michigan, Ann Arbor.

Trauma and Tumors in Industrial Medicine, November 6—medical discussion: Dr. Otto Saphir, professor of pathology, University of Illinois College of Medicine, Dr. Hamilton R. Fishback, associate professor of pathology, Northwestern University Medical School; legal discussion: Daniel D. Carmell Esq., member of Chicago Bar.

Scientific Tests in Evidence: Blood Grouping Tests in Disputed Paternity Cases; Chemical Tests for Intoxication, November 13—medical discussion: Dr. Israel Davidsohn, associate professor of medicine, University of Illinois College of Medicine, Clinical toxicologist, Michigan Department of Health; legal discussion: Fred E. Inbau Esq., professor of law, School.

All lawyers, physicians, students and others interested in medicolegal problems are cordially invited to attend. Early reservations for dinner will be appreciated.

MASSACHUSETTS

Changes in State Health Department.—Dr. Caroline A. Chandler has been appointed supervisor of clinics for crippled children in services for crippled children of the Massachusetts Department of Public Health, Boston. Prior to accepting a commission in the U. S. Public Health Service, Dr. Chandler was with the division of research in child development in the Children's Bureau. Dr. Roy F. Feemster was appointed director of the division of local health administration in the department of health. He will retain this office for the duration, after which he will return to his former position of director of the division of communicable diseases. Dr. Merrill E. Champion, former epidemiologist in the department, is now acting director of the division of communicable diseases. William H. Griffin, D.M.D., has been appointed to the Massachusetts Public Health Council by Governor Maurice J. Tobin. He succeeds Dr. Elmer S. Bagnall, Groveland, whose term of appointment expired in June. A. Laurence Corbman, D.D.S., formerly associate dental surgeon with the Office of Indian

Affairs of the U. S. Department of the Interior in South Dakota, has been appointed public health dental supervisor with the state department of health. He is assisting in a dental caries study authorized by the recent legislature, in which the use of fluorine for reducing caries among schoolchildren is being investigated. Dr. Charlotte Silverman is now with the department of health as epidemiologist in the division of communicable diseases. Prior to her appointment Dr. Silverman was senior assistant surgeon, U. S. Public Health Service Reserve, at the National Institute of Health, Bethesda, Md.

MICHIGAN

Human Problems in Industrial Employment.—"Human Problems in Industrial Employment" will be analyzed and discussed during a course of thirteen consecutive Wednesday evening conferences to be conducted by the Wayne University School of Occupational Health at the Hotel Wardell-Sheraton, Detroit. Topics to be considered in the conference include:

- September 19, Problems of Matching the Employee and the Job.
- September 26, Problems of Supervisor-Employee Relations in Job Adjustment.
- October 3, Human Relations in Industry.
- October 10, The Psychologist and Industrial Relations.
- October 17, subject not announced.
- October 24, The Psychiatrist and Industrial Relations.
- October 31, Techniques for Measuring and Evaluating Individual Behavior.
- November 7, Occupational Fatigue.
- November 14, Research Approach to the Study of Human Relations.
- November 21, Clinical Interpretation of Behavior in the Measure of Occupational Fitness.
- November 28, The Interdependence of Occupational and Nonoccupational Personal and Health Factors in Continued Job Adjustment.
- December 5 and 12, subjects not announced.

In a statement to the press Dr. Raymond Hussey, dean of the Wayne University School of Occupational Health, said that the program is offered as a community service. It is designed especially for physicians who are interested in the practice of medicine in its application to industrial health.

MINNESOTA

Operator of "Health Vaportorium" Sentenced.—On August 8 Dehlia C. McMahon, Minneapolis, pleaded guilty to the charge of practicing healing without a basic science certificate and was sentenced to one year in the Minneapolis workhouse. The sentence was suspended on condition that she close her place of business and refrain from attempting to practice healing. The defendant had operated a place known as the "Health Vaportorium," where she claimed to be giving treatments for such conditions as "sinus, colds, bronchitis, neuritis, arthritis, nervousness, poor circulation, constipation and so forth." The treatments, for which the defendant charged from two to five dollars each, consisted of a vaporized oil bath, massage and vitamins.

Courses for Physical Therapy Technicians to End.—The section on physical medicine at the Mayo Clinic, Rochester, will discontinue its regular emergency courses for the training of physical therapy technicians when the present class completes its training July 1, 1946. Attention will be directed then to the provision of graduate and refresher courses for physical therapy technicians who have previously completed a course in an institution approved by the Council on Medical Education and Hospitals of the American Medical Association. It is hoped to inaugurate this program in September 1946. A plan is also entered to replace the emergency courses for military physicians offered under the section on physical medicine throughout the war emergency, with graduate and refresher courses for army and navy medical officers returning from military service who may wish to continue in the field of physical medicine who may have worked in this field while in service.

NEW JERSEY

Personal.—Frederick W. Lorenz, Ph.D., assistant professor of poultry husbandry, University of California College of Agriculture, Davis, Calif., has been appointed to the research staff of the White Laboratories, Inc., Newark; he will be in charge of research in physiology and endocrinology.

Special Society Election.—Dr. Harry J. Perlberg, Jersey City, was elected president of the Radiological Society of New Jersey recently. Other officers include Drs. John L. Olpp, Englewood, vice president; Harry R. Brindle, Asbury Park, secretary, and William H. Seward, Orange, treasurer.

Survey of Hospital and Health Center Facilities.—The New Jersey State Commission on Postwar Economic Welfare is undertaking a statewide survey of hospital and health facilities and services as part of a national survey sponsored by

the Commission on Hospital Care, the New York Times reported July 22. Emil Frankel, director of research and statistics of the state department of institutions and agencies, will be director of the study, and William H. McDonald, Trenton, of the state department of health, will be assistant director.

NEW YORK

Staff Resigns at Guidance Center.—Plans for the operation of the Rochester Guidance Center, mental hygiene clinic for children, are under the consideration of the board of directors following the mass resignation of the entire clinic staff, which was in charge of Dr. Exie E. Welsch. All resignations are effective October 1, according to the Rochester Times Union. Newspapers indicated that criticism from agencies led to the clash between the staff and the board.

Louis Kress Made Director of Malignant Disease Institute.—Dr. Louis C. Kress, since 1919 associated with the State Institute for the Study of Malignant Diseases, Buffalo, has been named director of the institute, effective September 1. Dr. Kress, who graduated at the University of Buffalo School of Medicine in 1918, joined the institute staff in 1919 as voluntary assistant; in 1932 he was appointed assistant director of the newly created state division of cancer control, serving concurrently as chief surgeon of the institute. He has been director of the division since 1939.

New Offices of State Society.—The office of the Medical Society of the State of New York will be located on the seventh floor of the building at 292 Madison Avenue, New York 17. The society now has twice as much floor space as it had on the twenty-first floor of the building, where it has been located for the past five years. The new space is expected to be available soon after the first of the year. The house of delegates of the society will hold a meeting at the Statler Hotel, Buffalo, October 8-9. Plans are now going forward to increase the pages of the state journal in 1946. The following dates have been decided for various district meetings:

- First District, October 30, White Plains.
- Second District, October 24, U. S. Naval Hospital, St. Albans.
- Third District, September 20, Albany.
- Fourth District, September 21, Queensbury Hotel, Glens Falls.
- Fifth District, September 18, Oneida.
- Sixth District, September 26, Country Club, Cortland.
- Seventh District, September 27, Clifton Springs Sanitarium and Clinic, Clifton Springs.
- Eighth District, October 4, Hotel Statler, Buffalo.

New York City

Contributions of the War Effort to Medicine.—The eighteenth Graduate Fortnight of the New York Academy of Medicine, October 8-19, will be devoted to "Contributions of the War Effort to Medicine." Following the address of Dr. Cornelius P. Rhoads, acting president of the academy, the scientific program will open with the delivery of the Ludwig Kast Lecture by Col. William C. Menninger, M. C., on "Modern Concepts of War Neuroses." The lecture is in memory of Dr. Kast, who proposed the Graduate Fortnight. Other speakers will be:

- Dr. Thomas A. C. Rennie, What Can the Practitioner Do in Treating the Neuroses?
- Lieut. Col. Roy R. Grinker, M. C., Sedation as a Technic in Psychotherapy.
- Col. Howard A. Rusk, M. C., Planned Convalescence.
- Dr. David P. Barr, Physiologic and Psychologic Effects of Bed Rest.
- Dr. John H. Powers, Cooperstown, N. Y., Evaluation of Early Post-operative Activity.
- Dr. George W. Thorn, Boston, The Use of Human Serum Albumin in the Treatment of Edema of Renal and Hepatic Origin.
- Dr. Joseph Stokes Jr., Philadelphia, The Plasma Globulins in Prophylaxis and Treatment.
- Dr. Dickinson W. Richards Jr., Mechanism of Shock.
- Dr. S. Howard Armstrong Jr., Boston, Management of Blood Preservation and Blood Substitutes.
- Col. Daniel C. Elkin, M. C., Treatment of Peripheral Arterial Injuries (The Carpenter Lecture).
- Dr. Arthur W. Allen, Boston, Thrombosis and Embolism.
- Lieut. Comdr. Thomas I. Hoen (MC), Reconstructive Surgery of the Nerves.
- Dr. Philip D. Wilson, Reconstructive Surgery of the Joints.
- Dr. Virginia Kneeland Frantz, New Absorbable Hemostatic Agents.
- Dr. Jonathan E. Rhoads, Philadelphia, The Use of Penicillin and Streptomycin in Surgical Infections.
- Dr. James A. Shannon, Chemotherapy in Malaria.
- Dr. John P. Peters, New Haven, Nutritional Needs in Acute and Chronic Illness.
- Dr. Luther Emmett Holt Jr., Reevaluation of the Vitamins.
- Dr. Robert L. Levy, The Stimulus of War to Cardiology.
- Dr. Harold W. Brown, Filariasis.

The program will include a series of morning panel discussions on psychiatric rehabilitation, physical reconstruction, vascular surgery and ununited fractures. There will be clinics in the afternoon held at various hospitals in the city. Scien-

tific and drug exhibits and motion picture demonstrations and a special display of books illustrating the general subject of the fortnight will be shown as well as a practitioner's book shelf.

NORTH CAROLINA

Personal.—Eden Clark of Duke University, Durham, has been named chairman of the board of governors of the Association of Medical Illustrators (*THE JOURNAL*, August 4, p. 1040).

Undergraduate Award Given.—Dr. John P. McGovern, Washington, D. C., who graduated at Duke University School of Medicine, Durham, in June, was the first Duke recipient of the Borden Undergraduate Research Award in Medicine. The award was set up with a \$500 gift this year by the Borden Company Foundation of New York to stimulate productive research by undergraduate students. Dr. McGovern received the prize for his original investigation on whooping cough.

Radiologic Meeting.—The North Carolina Radiological Society will hold its fall meeting at the Watts Hospital, Durham, October 5-6. Among the speakers on the program will be:

Dr. George J. Baylin, Durham, Effects of X-Ray Therapy in Experimental Virus Pneumonia.

Dr. Gibbons W. Murphy, Asheville, Experiences in the Army of the United States.

Dr. Paul P. McCain, Sanatorium, Boeck's Sarcoid.

Dr. Jasper Lamar Callaway, Durham, Discussion of Cutaneous Manifestations of Sarcoid.

Dr. Robert J. Reeves, Durham, Discussion of Bone Lesions in Sarcoid.

Dr. Vincent W. Archer, Charlottesville, Va., Diagnosis of Bone Lesions in Childhood.

Dr. Hugh F. Hare, Boston, Treatment of Carcinomas of the Larynx.

Changes in Health Officers.—Dr. Alfred Mordecai has been appointed health officer for the newly created health department for Davie, Yadkin and Stokes counties, with headquarters in Winston-Salem. The change in the setup of the health department came about with the consolidation of the city and county units in Forsyth, with Dr. John Roy Hege resigning there to join the state health department at Raleigh.

—Dr. Gilcin F. Meadors Jr. has resigned as health officer of Lenoir County to report to the states relation division of the U. S. Public Health Service, Washington, D. C., effective August 10.—Dr. Hamilton W. Stevens, Jacksonville, director of the Onslow-Pender District Health Department, has resigned, effective September 30, to become director of the Wilson City and County health unit.

OHIO

Health Museum Buys Garfield House.—Trustees of Cleveland Health Museum have approved plans for purchase of the building formerly known as Garfield House, 8917 Euclid Avenue, occupied by the Cleveland Speech and Hearing Center. The new property will be used primarily to accommodate the Dickinson Collection of sculptural models of human reproduction recently acquired by the museum (*THE JOURNAL*, July 21, p. 893). It will also be used to augment space for other existing exhibits and for new exhibits planned to cover mental hygiene, industrial health and a new series pointing the way toward a healthier and happier old age. Additional space will be available for the health education laboratories, particularly the new plastics department, and extend the facilities for teaching in the postgraduate field of health education.

Western Reserve Plans New Psychiatric Program.—Approval has been given to the establishment of a psychiatric clinic at the University Hospitals, Western Reserve University, Cleveland, to provide treatment for civilians for a nominal fee and free treatment for servicemen and their families who are referred there by the American Red Cross. Establishment of the clinic is made possible through the Greater Cleveland Red Cross chapter, which has procured financial support for the part of the program applying to servicemen and their families. It is anticipated that some support for the civilian part of the program will be sought later through a public campaign. A new professorship of psychiatry has also been set up, the first incumbent to be Major Douglas D. Bond, head of psychiatry, U. S. Air Surgeon's Office, Washington, D. C., who will take over his new activities as soon as he is released from service. Major Bond in this position will serve as director of the clinic, which will be staffed by five psychiatrists, one psychologist and psychiatric social workers and nurses. For the present it will be housed in Lakeside Hospital. Eventually a new psychiatric building to cost about \$450,000 will be constructed to adjoin the other hospitals of the University Hospital group on the Western Reserve campus. The only member of Major Bond's staff thus far announced is Lieut. Col. Edward O'Neil Harper, who was with the Lakeside unit in the Pacific theater for three years.

The clinic will treat the more mild disorders, such as maladjustments and emotional difficulties. At all times in its planning and actual operations it is expected that representatives of the Red Cross will sit on the advisory committee and that Red Cross officials will be kept informed concerning personnel and operation in order that this cooperative project may continue efficiently and with the greatest benefit to those whom it seeks to serve. The new clinic is said to represent a pioneer project as far as the Red Cross is concerned.

PENNSYLVANIA

Philadelphia

George Meeker Dies.—George H. Meeker, Ph.D., from 1918 to 1941 dean of the Graduate School of Medicine of the University of Pennsylvania, died at Hunt's Lake, N. J., September 4, aged 74. Dr. Meeker received his Ph.D., at Lafayette College, Easton, Pa., in 1898 and his Pharm.D. at the Medico-Chirurgical College in Philadelphia in 1906. He had served as professor of chemistry at the University of Pennsylvania School of Medicine from 1916 to 1940. He aided in the establishment and became the first dean of the Graduate School; he also founded the department of pharmaceutical chemistry at the university in 1907. He was director of the Graduate Hospital from 1924 to 1928 and was prominently known as an expert on toxicology.

SOUTH CAROLINA

Postgraduate Assembly.—The Piedmont Post Graduate Assembly and the Fourth District Medical Society are cooperating in the following program at the Anderson County Hospital, Anderson, September 18:

Dr. A. Benson Cannon, New York, Management of Some Common

Skin Diseases and Presentation of Clinical Cases.

Col. Charles T. Young, M. C., The Army's Appraisal and Management

of Battle Fatigue.

Dr. James Elliott Scarborough Jr., Atlanta, Ga., Management of

Melanoma.

Dr. Oscar L. Miller, Charlotte, N. C., Orthopedic Problems Which the

General Surgeon and Family Doctor Should Handle.

At the banquet session in the Calhoun Hotel, with Dr. Joseph Decherd Guess, Greenville, as toastmaster, the speakers will be Dr. Scarborough on "Some General Remarks on Cancer" and Dr. Miller, who will give a biographic sketch of "Dr. Oliver M. Doyle."

UTAH

Program in Child Psychiatry.—The Rockefeller Foundation has given funds to the University of Utah School of Medicine, Salt Lake City, to establish a program in child psychiatry. Dr. Reynold A. Jensen, associate professor of neuropsychiatry and pediatrics, University of Minnesota Medical School, Minneapolis, in charge of the child psychiatric clinic, University Hospitals, Minneapolis, is in Salt Lake City on the grant for a period of two months to create interest in the establishment of a child psychiatric program there.

Anonymous Donation Sets Up Lectureship.—An anonymous donor has given funds to the Utah Medical Foundation to present a series of lectures on current problems in pediatrics, the first of which was recently given by Dr. Joseph Stokes Jr., William H. Bennett professor of pediatrics, University of Pennsylvania School of Medicine, Philadelphia. Dr. Stokes's subjects were "The Study of Hepatitis" and "Some Uses of Gamma Globulin in Hepatitis and Other Infectious Diseases." The second speaker in the series was Dr. Alexander Ashley Weech, B. K. Rachford professor of pediatrics, University of Cincinnati College of Medicine, who spoke on "Physiologic Consequences of Inadequate Dietary Protein" and "The Role of Cortical Development in Determining the Behavior of Infants." The Utah Medical Foundation was recently established at the University of Utah School of Medicine with a gift by the first graduating class of the four year school (*THE JOURNAL*, August 25, p. 1240).

WEST VIRGINIA

Personal.—Dr. Paul H. Harmon, chief of the orthopedic department of the Guthrie Clinic at Robert Packer Hospital, Sayre, Pa., has been appointed medical director of the Morris Memorial Hospital, Milton, effective August 1.—Mrs. Ruth J. Franz, Milwaukee, has been appointed director of the bureau of public health education in the state health department, succeeding the late Dorothea Campbell, Charleston. Mrs. Franz, who is a graduate of the University of Michigan and who has completed a course in public health education at the School of Public Health at Ann Arbor, has recently been doing field health work for the Michigan Department of Health.

Membership of Advisory Legislative Committee Completed.—The membership of the advisory committee to the legislative interim committee studying public health problems (THE JOURNAL, May 5, p. 44) was recently completed, when Governor Clarence W. Meadows named business and professional men and women as members of the group. Eight physicians were appointed by the governor several weeks ago as members of the advisory committee (THE JOURNAL, June 23, p. 606). Dr. William R. Laird, Montgomery, has been named as the governor's personal representative in the field of medicine. Henderson Peebles, Charleston, will represent business, and Mrs. D. W. Stubblefield, Charleston, the public at large. Labor representatives include John B. Easton, Charleston, C. I. O.; Volney Andrews, Charleston, A. F. of L., and George J. Titler, Beckley, United Mine Workers of America. H. B. Crow, Weirton, is the industrial representative and John J. Foster, Holden, was named for mines and mining. O. W. Van Petten, Charleston, will represent the oil and gas industry.

PUERTO RICO

Hospital Construction.—The building of three hospitals is under consideration by the committee on design of public works of Puerto Rico, one in Ponce, one in Mayaguez and one in Guayama. The Ponce Charity Hospital is to be an eight story structure to cost about three million dollars and to have a capacity of about 600 beds. The Mayaguez institution is to have 500 beds and cost about two million dollars, while the Guayama Hospital is to cost about one million and have 300 beds.

GENERAL

Your Doctor Speaks.—Every physician in the United States will receive during the coming months copies of a new publication entitled "Your Doctor Speaks." The book, issued by the Upjohn Company, manufacturers of pharmaceuticals, contains a series of health messages which are a part of the health campaign being run monthly in various popular periodicals.

Industrial Safety Tomorrow.—The National Safety Council has released a sixteen page pamphlet entitled "Industrial Safety Tomorrow," outlining a specific program to help industry meet an impending increased accident toll. Preparation of the pamphlet was handled by a special committee on postwar industrial safety and represents the contributions of thirty-eight national organizations interested in industrial safety.

Expanded Facilities Approved to Produce Streptomycin.—On August 1 the War Production Board approval of priorities for plant and equipment materials was received by Merck & Company, Rahway, N. J., to permit the construction of special facilities for the production of streptomycin. The production unit will be erected at the company's Stonewall Plant at Elkton, Va., and a unit for drying and packaging the drug at the company's main plant at Rahway. Total cost will approximate \$3,500,000. The new plant is expected to go into production early in 1946.

Pan American Congress of Otolaryngology Postponed.—Because the cancellation of the 1945 annual meeting of the American Academy of Ophthalmology and Otolaryngology was necessary, the Pan American Congress of Otolaryngology and Broncho-Esophagology has also been postponed to the following year. The academy committee is preparing meanwhile a directory of otorhinolaryngologists in the Americas, which will include not only a list of the names and addresses of the qualified specialists in the various countries of North, Central and South America but also a list of the societies of otorhinolaryngology, with their present officers; the journals of otorhinolaryngology and their editors-in-chief, and the faculties of medicine which have chairs of otorhinolaryngology, with the name of the present incumbent.

Pan American Congress of Ophthalmology.—The official meeting place of the second Pan American Congress of Ophthalmology, which will take place in Montevideo, Uruguay, November 26-December 1, is the Municipal Hotel "Miramar" on Carrasco Beach. Reservations should be made before October 1 through Dr. Conrad Berens, 301 East 14th Street, New York 3. Any one who wishes to stay in some other hotel should make reservation requests before October 1 to the treasurer of the congress, Dr. Julio A. Sicardi, Agrupacion Universitaria, Ave. Agracida 1464, P. 13, Montevideo. The registration fee for members of the congress is \$11 U. S. money (\$20 Uruguayan) and for others in the party who wish to be included in the social events \$5.50 U. S. money, per

person. These fees may also be paid in advance to Dr. Berens. Because of travel conditions, it was not possible to make arrangement for those attending the congress from the United States to go in a group. The Pan American Airways and the American Express Company will cooperate to do everything possible to work out transportation plans to meet individual requirements. Dr. Harry S. Gradle, Chicago, is president of the congress.

"The Constant Invader" Theme of New Radio Series.

—The first major nationwide effort by tuberculosis associations to use radio as a channel for health education will be made this fall, when "The Constant Invader," a series of thirteen recorded dramatic shows, goes on the air from approximately 250 stations throughout the country. The series, produced by the National Tuberculosis Association for affiliated associations, dramatize the ways and means of preventing and controlling tuberculosis. Dr. Archibald J. Cronin, author, is the narrator of the series, Hu Chain, New York, the writer producer and Ben Ludlow the composer conductor. The thirteen dramatic shows portray consecutively the advances in medicine and surgery in the treatment of tuberculosis, the role of the family doctor in the tuberculosis campaign, the ways in which community agencies work together toward the solution of the tuberculosis problem, the work of the public health nurse in a rural community, the necessity of tuberculin testing in schools, the "hows" of an industrial x-ray survey, the necessity of examining family contacts, modern sanatorium care, a typical college health program, tuberculosis as a problem among old people, the value of rehabilitation, the "hows" and results of health education, and medical research.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended September 1 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Division and State	Poliomyelitis		Division and State	Poliomyelitis	
	Week Ended	Week Ended		Week Ended	Week Ended
	9/1, 1945	9/2, 1944		9/1, 1945	9/2, 1944
New England States:			South Carolina ..	12	4
Maine	3	1	Georgia	6	8
New Hampshire ..	3	11	Florida	4	2
Vermont	5	7	East South Central States:		
Massachusetts ..	32	35	Kentucky	2	34
Rhode Island	0	1	Tennessee	23	5
Connecticut	20	20	Alabama	2	2
Middle Atlantic States:			Mississippi	3	7
New York	138	666	West South Central States:		
New Jersey	96	67	Arkansas	4	3
Pennsylvania	61	162	Louisiana	7	1
East North Central States:			Oklahoma	16	2
Ohio	33	105	Texas	33	8
Indiana	22	27	Mountain States:		
Illinois	94	37	Montana	0	
Michigan	13	120	Idaho	3	1

Nebraska	15	8	Washington	22	12
South Atlantic States:			Oregon	5	11
Delaware	4	4	California	33	10
Maryland	3	47	Total	917	1,682
Dist. of Columbia	8	22	First 35 weeks:		
Virginia	32	65	1945 and 1944 ..	6,126	9,474
West Virginia ..	1	14	Median, 1940-1944	4,026	
North Carolina ..	10	41			

The seasonal peak of poliomyelitis this year for the country as a whole has probably been reached, although a few areas, especially in the Northern states, may report some increased incidence during the next few weeks. The largest weekly number of reported cases, 931, was for the week ended August 25, as compared with a peak of 1,682 cases for the week ended Sept. 2, 1944. If cases were recorded by date of onset rather than by date of report to the local health officers, the peak of incidence would probably be a week or ten days earlier.

CORRECTION

The Therapeutic Uses of Radioactive Phosphorus.—In the editorial with this title in THE JOURNAL, July 28, page 954, appears a statement to the effect that complications such as leukemia may be produced when this form of therapy is employed in the treatment of polycythemia vera. The word used should have been leukopenia. Complications such as leukopenia, thrombocytopenia or anemia not infrequently may be observed in patients with polycythemia vera if the dosages of radioactive phosphorus administered are large.

Aug. 18, 1945.

The Teaching and Practice of Chemical Pathology

Because of the present unsatisfactory position of chemical pathology, a committee of the chemical pathologists of the London teaching hospitals has prepared a memorandum on the subject. The members agree with the recommendation in the Goodenough report that chemical pathology should form a separate department and be under the direction of a professor, reader or senior lecturer. To this they would add that the chemical pathologist should be a full member of the medical committee of his hospital. Undergraduate teaching in chemical pathology should be given in the form of a short introductory course at the beginning of the clinical period, with other lectures over the remaining clinical years. The committee differs from the Goodenough proposal which allots routine chemical work to the clinical pathologist, because the chemical pathologist would be largely cut off from the principal source of his inspiration, and his teaching of the basic principles and routine methods would tend to lose contact with current practice. If, for example, no routine blood urea estimations were performed in his department, both the technic and the interpretation of this test would eventually become remote from his personal experience. The standard of chemical work would become lower and a retrograde step would be taken against the tendency to specialization in pathology, which is inevitable. In a hospital of 1,000 beds the routine work in hematology and bacteriology will be so much that the addition of routine chemical tests would be an excessive burden. A closer liaison between the preclinical biochemical and the chemical pathology departments in the medical schools is advised.

The following curriculum, based on a total of twenty-four hours' instruction during the clinical period, is recommended in the report: 1. An introductory course of six hourly periods in the first clinical year, dealing with general principles and including instruction on collection of specimens and urine testing. 2. A general course of eighteen hourly periods during the second and third clinical years, covering the whole subject of the application of chemical methods to clinical problems. 3. A limited number of lectures on special aspects and recent advances during the preregistration year.

Proposed Formation of a Group of Dermatologists Within the British Medical Association

A number of members of the British Medical Association who are dermatologists have petitioned the association for the formation within it of a group of dermatologists. They are engaged in a specialized branch of which the importance is becoming increasingly recognized, but the number in one division of the association is too small to put forward the medico-political problems of the specialty adequately. They therefore hold that the formation of a group of those whose work is exclusively dermatologic would be an advantage both to the group and to the association.

British Medical Association Passes the 50,000 Mark

The British Medical Association has passed the mark of 50,000 members for the first time. On Sept. 2, 1939 the number was 39,121; in 1942, 41,239, and in July 1945, 50,032. The great increase in the last three years seems to have been largely due to the Beveridge scheme for a national health service, which threatened to convert the doctors into state officials. The *British Medical Journal* looks back with gratitude to its founder, Dr. Charles Hastings, who with his colleagues propounded the

objects of the association, which have stood the test of time. Beginning in 1832 with the small group of 50, the membership had grown to 500 in 1836, to 1,010 in 1839, to 5,400 in 1873, to 10,050 in 1883, to 16,000 in 1895, to 20,993 in 1906 and to 30,524 in 1925. The objects of the association, as laid down by its founder, were the advance of medical science and the maintenance of the honor of the profession by promoting voluntary intercourse and free communication of its members.

MOSCOW

(From a Special Correspondent)

Aug. 21, 1945.

The Moscow Medical Institute

Tsarist Russia's thirteen faculties of medicine and 1,800 students have been increased under the Soviet rule to seventy-two medical institutes with a student body of 115,000. Russia's 20,000 doctors in 1913 have now grown to 130,000. Still the number of doctors is not adequate to meet the nation's needs and to staff its expanding network of medical institutes. These graduate as many as 20,000 doctors a year. Following is a description of the type of work performed by one of these schools. The Moscow Medical Institute, of which Andrei Likhachev is director, is celebrating its 180th anniversary this year. A number of Russian scientists who have added brilliant pages to medical history received their training here. Among these may be mentioned the surgeon Nikolai Pirogov and the internist Sergei Botkin. Ivan Sechenov, author of "Brain Reflexes," was one of its teachers. The institute has made valuable contributions in every field of theoretical and practical medicine. The student body today numbers 4,000. The first two years are devoted to the study of anatomy, physiology, histology, biology and biologic chemistry. Beginning with the third year, students are introduced to clinical work. After receiving their general training they specialize in hospitals and clinics in accordance with their inclinations and abilities.

On the teaching staff are men of the type of Nikolai Burdenko, chief surgeon of the Red army; the pathologist Alexey Abrikosov, who has trained an army of pathologists in the course of his thirty-five years' work at the institute, and Boris Zbarsky, who embalmed the body of Lenin and is now teaching biochemistry. All these men have had the highest civilian award, Hero of Socialist Labor, conferred on them. The staff numbers 70 professors, 100 docents and over 250 instructors. Eleven are members of the Medical Academy of Sciences.

The course of study was increased this year from five to six years. There are no tuition fees; 95 per cent of the students receive government stipends. Sixteen of the best students receive the Stalin scholarship. Over 30 per cent live in institute dormitories. In addition to their regular studies students may attend thirty circles of study in various specialized scientific fields. Five hundred students working in these circles are given opportunity to engage in independent research work.

Very popular is our "Free Day" club, which is conducted by the students and teachers and which arranges concerts, lectures by poets and novelists, and debates.

Students who attain a high average and display ability for research and teaching are given an opportunity to continue their work at the institute in a three year postgraduate course, during which they work in laboratories and clinics under the guidance of professors and write their theses for the degree of candidate of science. Throughout their postgraduate period students receive government stipends large enough to enable them to devote themselves entirely to their work.

The institute has trained 34,000 doctors in its one hundred and eighty years of existence. During the war, Academician Burdenko set up an experimental station in the institute to test new drugs and methods of treatment of wounds and of chemical and thermal burns.

The Chair of Food Hygiene developed recipes for so-called supplements, which increase the assimilability and nutritive value of various food concentrates. The Chair of Communal Hygiene has developed methods of simplifying chlorination of the water supply for army field units.

The institute graduated 3,300 doctors during the war. In their leisure time students work with enthusiasm in hospitals and take an active part in hygienic inspection of the cities. Many of our students have won government medals and orders. The institute was awarded the Order of Lenin in 1940, on the occasion of its 175th anniversary, in recognition of the services its teaching staff has rendered in training medical men and in advancing medical science.

BOLIVIA

(From Our Regular Correspondent)

LA PAZ, Aug. 14, 1945.

Pharmacies and Drug Market in Bolivia

For the needs of the approximately three million inhabitants of Bolivia there is a total of seventy-two registered drugstores, fifty-eight of which are located in the district capitals and only fourteen in rural areas, where the doctors have to do their own dispensing of drugs. Every drugstore must have a registered pharmacist in charge, strict supervision being exercised in this respect by the National Health Department.

Most of the drugs are imported but there are also a few national manufacturers. The Public Health Department operates a bacteriologic laboratory, producing appreciable quantities of good vaccines against smallpox, whooping cough, typhoid and plague for free distribution throughout the country. The Army Health Service operates drugstores and laboratories of its own. Large quantities of quinine sulfate and totaquine for home use and for export are produced by a government owned plant. There are some forty wholesale stores which are importers of remedies from abroad.

Up to the outbreak of the war German manufacturers such as Bayer, Schering and Knoll were firmly established on the Bolivian market and had practically no competitors. In 1939 most of them started production in their laboratories in Argentina, Brazil and Chile, but they had soon to curtail sales, as they ran short of raw materials from Germany. In 1942 American manufacturers, who had not been interested in this market before, started sending their drugs here; because of their quality, low prices and neat appearance they were immediately accepted by physicians and public alike. Today most of the larger American manufacturers as well as Brazilian, Argentine and Chilean producers are selling regularly their proprietary articles, especially vitamins, to a public which has become lately quite "vitamin conscious."

There is unfortunately a lack of certain sanitary goods such as surgical gloves and instruments.

In many a remote village, which had never known a doctor or drugstore, there practice medicine-men or witch doctors. The profession is usually passed on from father to son. Carrying his "drugstore" in a bag, this "doctor" comes to the sick man's house, bringing leaves, roots, bulbs, seeds and barks. Some of these remedies are quite efficient. It is noteworthy that it was these practitioners who, according to records, were first to use cinchona bark in the treatment of malaria. Many another drug from their "pharmacopeia" has later been officially accepted by the modern pharmacologists all over the world—to mention just one, the leaves of *Erythroxylon coca*, the "Divine plant of the Incas."

The medicine-man's reputation is rapidly vanishing now that some physicians are starting to work in the rural areas. However, to get the public there to trust him, the recently arrived physician has to prove first that his modern science and drugs are more efficient than the medicine-man's cures.

BELGIUM

(From a Special Correspondent)

Aug. 6, 1945.

Royal Academy of Medicine

The Royal Academy held its first public session since the liberation of Belgium on February 24. The president, Professor d'Hollander, made an address on the occasion of the liberation of the territory from enemy occupation. Professor Bruynoghe, secretary, read a moving obituary notice recalling the great merits of Professor Delrez as teacher, surgeon, scientist and academicien. He emphasized his patriotic sacrifices during the war of 1914-1918 and during the present war and stressed his important contributions to the surgical and scientific activities of the Ocean Ambulance.

The following subjects came up for discussion: low tension in electrocardiography, presented by F. Dauwe; the surgical treatment of essential hypertension, by Jean Govaerts, and the anti-Rh factor and erythroblastosis, by R. Bruynoghe, J. Hoet, De Somer and Vanden Broecke. In a subsequent session Dr. Lauwers read a paper on the intracarotid injections of procaine and other substances in the treatment of epilepsy.

Social Insurance

A struggle is in progress between the government and the medical profession. In effect, the proposed law of social insurance involves the loss of almost all of free practice. In a declaration Dr. Glorieux, president of the Belgian Medical Federation, said "At present there are in Belgium 2,600,000 persons under social insurance. If the draft of the law is adopted, it will mean that 96.5 per cent of the population is destined to become so. This condition will lead inescapably to state medicine. This must not happen. Suppress your motives of discord." France is undergoing a like experience and the disorganization of the medical profession has permitted the adoption of this law. The Belgian Medical Federation is organizing to resist this plan, which would transform the doctor into a functionary of the state.

Acetylcholine and Paroxysmal Tachycardia

The Belgian Society of Cardiology heard a communication by Segers, J. Lequime and H. Denolin on the arrest of crises of paroxysmal tachycardia by the intravenous injection of acetylcholine. The acetylcholine was administered intravenously, the dose varying between 0.01 and 0.10 Gm. dissolved in a 5 per cent solution. The authors were able to arrest with this method sixty-five attacks of tachycardia in 8 different subjects. There were no failures. The arrest of the attack was always prompt, less than thirty seconds after the termination of the injection.

Marriages

CLARENCE RAY LEININGER JR., Trenton, Mo., to Miss LoDonna Watson of Rexburg, Idaho, in Chicago June 13.

ROBERT ALEXANDER PRINGLE, Charleston, S. C., to Miss Barbara Bernice Baldock of Knoxville, Tenn., recently.

WALTER CLEVELAND FITZGERALD, Crewe, Va., to Miss Martha Ann BonDurant of Princeton, W. Va., July 1.

JOHN WILLIAM MURPHY JR., Kirkwood, Mo., to Miss Elizabeth Anne White of Norfolk, Va., in June.

JOHN EMORY HOLLER, Columbia, S. C., to Miss Edith Wilhelmna Stuckey of Bishopville, June 29.

RICHARD DEMME BAUER to Miss Lourainia Vrooman, both of Philadelphia, June 9.

MIGUEL DROBINSKY, Estelline, S. D., to Miss Lillian Starr of Chicago, June 23.

MILTON PLAFKER, New York, to Miss Elaine Kastil of Chicago, June 17.

Deaths

Edward Blanchard Hodge ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1899; born in Burlington, N. J., Aug. 21, 1875; at one time associate professor of surgery at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; member of the founders group of the American Board of Surgery; member of the American Surgical Association; vice president of the College of Physicians of Philadelphia; served in France during World War I; formerly on the staffs of the Presbyterian, Germantown, Children's and University of Pennsylvania hospitals, in addition to serving as a member of the board of Children's Hospital; served on the staff of Chester County Hospital in West Chester; a trustee of Princeton University, Princeton Theological Seminary and Lincoln University, Oxford, Pa.; member of the board of the Northern Trust Company; member of the board of the Children's Seashore House, Atlantic City; a director of the Southeastern chapter of the American Red Cross; died June 19, aged 69, of myocardial infarction.

Josef Benediktus Nylin ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1910; born in Sweden in 1874; served as assistant professor of physical therapy at the Woman's Medical College of Pennsylvania; at one time on the faculty of his alma mater and the Graduate School of Medicine of the University of Pennsylvania; member of the American Congress of Physical Therapy, the International Society of Medical Hydrology, London, England, Pennsylvania Physical Therapy Association, Pathological Society of Philadelphia and the American Swedish Historical Museum, of which he had been a trustee; chief of the department of physical therapy at the Hospital of the University of Pennsylvania; consultant in physical therapy at the Shriners' Hospital for Crippled Children; author of a chapter on "Hydrotherapy" in volume III of the Principles and Practice of Physical Therapy; died June 23, aged 71.

Marshall William McDuffie, New York; New York Homeopathic Medical College and Hospital, New York, 1904; born in Henderson, N. C., April 18, 1882; member of the Academy of Pathological Science, New York Academy of Sciences, American Association for the Advancement of Science and the American Institute of Homeopathy; president of the New York Homeopathic County Medical Society, 1926-1927; formerly assistant professor of gynecology at his alma mater; served as attending surgeon and chairman of advisory board and executive committee of the Park West Hospital; for many years on the staffs of the Metropolitan Hospital, Flower and Fifth Avenue Hospitals and St. Gregory's Hospital; died July 23, aged 63, of heart disease.

Charles Eaton Phillips ☉ Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; born in Millington, Ill., Feb. 3, 1877; fellow of the American College of Surgeons; founder of the Los Angeles Surgical Society; for eight years surgeon in Panama when the canal was built; served in the medical corps of the U. S. Army with the rank of major during World War I; lecturer and instructor to medical conference groups at military posts during World War II; senior surgeon at the Los Angeles County Hospital for twenty-four years; visiting surgeon, Hospital of the Good Samaritan, Cedars of Lebanon Hospital and Presbyterian Hospital-Olmsted Memorial; died June 14, aged 68.

Edward M. Amos, Indianapolis; Central College Physicians and Surgeons, Indianapolis, 1891; born in Kirkland, Ind., Feb. 14, 1866; member of the American Medical Association; honorary member of the Indiana State Medical Association; served as president of the Indiana Tuberculosis Association and of the Marion County Tuberculosis Association; member of the staff and formerly directed the tuberculosis clinic at the City Hospital; member of the staff and a trustee of the Sunnyside Sanatorium; on the staffs of St. Vincent's Hospital and the Methodist Hospital, where he died July 19, aged 79, of coronary occlusion.

Donald Adelbert Bartley ☉ Indianapolis; Indiana University School of Medicine, Indianapolis, 1914; specialist certified by the American Board of Ophthalmology; associate professor of ophthalmology at his alma mater; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Indianapolis Ophthalmological and Otolaryngological Society; served in the medical corps of the Royal Army during World War I; on the staffs of the City Hospital, St. Vincent Hospital and the Methodist Hospital, where he died June 16, aged 58, of cardiac failure.

Leslie Shellabarger Brookhart ☉ Cleveland; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; veteran of the Spanish-American War and World War I; member of the Association of Military Surgeons of the United States; a charter member of the Cleveland Health Museum for many years; industrial physician and surgeon for the American Steel and Wire Company; staff member of St. Alexis and Woman's hospitals; for many years on the staff of St. Luke's Hospital, where he died June 24, aged 64.

Charles F. Anck, Philadelphia; Medico-Chirurgical College of Philadelphia, 1891; died April 2, aged 72, of intestinal obstruction, ruptured diverticulum of the sigmoid colon and peritonitis.

Hyman Bernstein ☉ Pittsburgh; Georgetown University School of Medicine, Washington, D. C., 1904; served on the staffs of the Montefiore and Passavant hospitals; died June 16, aged 68, of coronary disease.

Louis Bernstein, New York; University and Bellevue Hospital Medical College, New York, 1904; died April 24, aged 66.

Joseph Blickensderfer, Lebanon, Mo.; Omaha Medical College, 1887; served as city and county health officer while in New Philadelphia, Ohio; died in the Louise G. Wallace Hospital May 26, aged 82, of myocarditis.

Donald Hunter Clark, Redlands, Calif.; University of Texas School of Medicine, Galveston, 1899; died in the Community Hospital April 12, aged 69.

Angus Bertram Cowan ☉ Fresno, Calif.; Cooper Medical College, San Francisco, 1893; member of the American Academy of Pediatrics; specialist certified by the American Board of Pediatrics, Inc.; on the staffs of Burnett Sanitarium, General Hospital of Fresno County and St. Agnes Hospital, where he died April 20, aged 74, of congestive heart disease and coronary sclerosis.

Charles John Drueck ☉ Chicago; Northwestern University Medical School, Chicago, 1896; for many years associate professor of rectal diseases at the Post-Graduate Hospital and Medical School; at one time professor of physiology at the Illinois School of Dentistry; served on the staffs of the Chicago Memorial and Illinois Masonic hospitals; author of "Fistula of the Anus and Rectum"; died in St. Luke's Hospital June 30, aged 72, of peritonitis following an operation for carcinoma of the stomach.

Edwin Delta Ebricht ☉ Wichita, Kan.; Kansas City (Mo.) Medical College, 1896; past president of the Kansas Medical Society and Sedgwick County Medical Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association in 1926; served during World War I; on the staff of the Wesley Hospital; on the staff of the Wichita Hospital, where he was orthopedist in charge of Kansas Crippled Children Commission work and where he died May 13, aged 71, of carcinoma of the liver.

Harry M. W. Edmonds, Berkeley, Calif.; the Hahnemann Medical College and Hospital, Chicago, 1892; died April 4, aged 82.

Clarence Frederick Fowler ☉ Galveston, Texas; University of Texas School of Medicine, Galveston, 1914; on the staff of St. Mary's Infirmary; died June 30, aged 56, of coronary occlusion.

James C. Higgins, Philadelphia; Medico-Chirurgical College of Philadelphia, 1904; died in the Philadelphia General Hospital April 10, aged 69, of arteriosclerotic heart disease and auricular fibrillation.

Francis Bennett Hitchcock, Lewisburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1925; member of the American Medical Association; served on the staffs of the George F. Geisinger Memorial Hospital in Danville and the Evangelical Hospital; county medical director; vice president of the school board; died in Lake Worth, Fla., June 24, aged 56, of coronary thrombosis.

Leon Kimball Leigh, Chicago; National Medical University, Chicago, 1898; died June 13, aged 74, of coronary thrombosis and nephritis.

Everett Newton Lipe ☉ Fairfax, Okla.; Memphis (Tenn.) Hospital Medical College, 1902; served during World War I; died in St. Mary's Hospital, Rochester, Minn., June 1, aged 66, of thrombosis of the middle cerebral artery.

Lionel Hartsfield Love, Pacific Grove, Calif.; Columbia University College of Physicians and Surgeons, New York, 1898; died April 21, aged 73.

Victor Mahrer, Holland Patent, N. Y.; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1906; died in the Faxton Hospital, Utica, April 23, aged 64.

Jacob Manting ☉ Detroit; University of Michigan Medical School, Ann Arbor, 1920; fellow of the American College of Surgeons; member of the surgical staffs of the Harper and Delray hospitals; died in Bloomfield Hills, Mich., June 14, aged 50, of heart disease.

Benjamin Meredith McIntire, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1911; member of the American Medical Association; served overseas during World War I; died May 27, aged 61.

Domenico Merendino, New Orleans; Regia Università degli Studi di Palermo. Facoltà di Medicina e Chirurgia, Italy, 1900; died in the Hotel Dieu May 6, aged 72, of cerebral hemorrhage and arteriosclerotic heart disease.

John W. Moffatt, Marietta, Ohio; Starling Medical College Columbus, 1891; died June 8, aged 79, of heart disease.

Horace Cary Morrow, Austin, Texas; Pulte Medical College, Homeopathic, Cincinnati, 1878; served as a member and as president of the Texas Board of Medical Examiners; died in Dallas June 26, aged 91, of myocardial degeneration.

Joseph Porter Myers, Edinburg, Ind.; Louisville (Ky.) Medical College, 1898; died June 10, aged 70, of coronary occlusion.

Henry Newton Nipple, Selinsgrove, Pa.; Jefferson Medical College of Philadelphia, 1898; died in the Community Hospital, Sunbury, April 19, aged 73, of myocarditis and bronchial asthma.

Cyrus W. Noble, Toledo, Ohio; Eclectic Medical Institute, Cincinnati, 1897; author of two books of verse entitled "Memories" and "Word Pictures"; died May 29, aged 71.

John W. Pierce, Suffolk, Va.; Howard University College of Medicine, Washington, D. C., 1910; died in the Lakeview Hospital May 28, aged 65, of heart disease.

Benjamin Franklin Steely, Louisville, Ill.; Hospital College of Medicine, Louisville, Ky., 1907; member of the American Medical Association; died in St. Anthony's Hospital, Effingham, May 18, aged 64, of heart disease.

William Paul Stetson, New Haven, Conn.; University of Vermont College of Medicine, Burlington, 1938; member of the American Medical Association; instructor of physical hygiene at the Arnold College; on the staff of the Grace Hospital, where he served an internship; flight surgeon for civilian pilots; member of the health committee of the New Hampshire Junior Chamber of Commerce; died June 21, aged 32, of seminoma of the right testicle with metastases.

LIEUT. ROBERT S. HURLBUT
(MC), U.S.N.R., 1912-1945

LIEUT. HELMUT WILLIAM FESCA
M. C., A. U. S., 1917-1944

LIEUT. BURTON ADAM HALL, M. C.,
A. U. S., 1912-1944

Fred Porter Nevius ☉ Oakland, Calif.; Michigan College of Medicine and Surgery, Detroit, 1906; served during World War I; for many years city physician of Antioch; died June 14, aged 62.

Emma Barker Steyner, Williamson, N. Y.; the Hahnemann Medical College and Hospital, Chicago, 1884; died May 20, aged 85, of carcinoma of the large bowel and malignant cachexia.

KILLED IN ACTION

Robert Satterlee Hurlbut, Cambridge, Mass.; Harvard Medical School, Boston, 1938; diplomate of the National Board of Medical Examiners; served an internship and residency at the Massachusetts General Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Oct. 19, 1942; following service at the Chelsea Naval Hospital at the Office of Medical Officer Procurement, First Naval District, and as physician at the Harvard Naval Dispensary, began sea duty on the *Halligan* in September 1943; saw service in the Atlantic and in North Africa; was in invasion actions for more than a year in the Pacific; promoted to lieutenant; killed in action March 26, aged 33, when the destroyer *Halligan* was sunk off Okinawa.

Helmut William Fesca, San Francisco; University of California Medical School, San Francisco, 1943; interned at the Franklin Hospital; member of the American Medical Association; began active duty as a first lieutenant

in the medical corps, Army of the United States, on Dec. 26, 1943; killed in France July 27, 1944, during an American dive bomber attack on a German train in which he was a prisoner, aged 27.

Burton Adam Hall, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1938; interned at St. Luke's and Children's Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 24, 1942; attached to the air corps; in November 1942 graduated as a flight surgeon from the School of Aviation Medicine, Randolph Field, Texas; assigned to the first medical air evacuation transport squadron to function in any theater of war; aboard a transport aircraft which departed Jan. 13, 1943, for Guadalcanal, Solomon Islands, and failed to reach its destination en route to Efate, New Hebrides; posthumously awarded the Purple Heart; officially declared dead Jan. 13, 1944, aged 31.

Mack Milton Strickland, Selma, Ala.; University of Alabama School of Medicine, 1900; died in the King Memorial Hospital May 16, aged 69, of cardiac failure due to hypertensive heart disease.

Albert Tower Summers, Mattoon, Ill.; Kentucky School of Medicine, Louisville, 1903; member of the American Medical Association; on the staff of the Memorial Methodist Hospital; died in the Doctors Hospital, Washington, D. C., June 2, aged 67, of coronary thrombosis.

William Zerns Suplee, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1897; died June 1, aged 70, of heart disease.

Merrick Ward Swords, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1907; formerly secretary of the state board of health; for many years associated with the city board of health; in 1916 appointed chief of staff of the genitourinary department of the Charity Hospital; served as associate editor of the *Southern Medical Journal*; died in June, aged 61, of coronary thrombosis.

Charles A. Talbot, Waynesville, Mo.; Northwestern University Medical School, Chicago, 1904; member of the American Medical Association; died in Pryor, Okla., July 31, aged 65, of cerebral hemorrhage.

James J. Toalson, East Alton, Ill.; St. Louis College of Physicians and Surgeons, 1897; served on the staff of St. Francis Hospital in Peoria; died May 30, aged 72, of cerebral arteriosclerosis.

Fletcher Jackson Van Meter ☉ Talmage, Calif.; Drake University College of Medicine, Des Moines, 1906; fellow of the American Psychiatric Association; served during World War I; formerly on the staffs of the Clarinda (Iowa) State Hospital and the Norwalk State Hospital in Norwalk; clinical director of the Mendocino State Hospital; died August 4, aged 61, of coronary occlusion.

William George Wander ☉ Detroit; Washington University School of Medicine, St. Louis, 1919; member of the American Academy of Dermatology and Syphilology; past president of the Detroit Dermatological Society; associate dermatologist at St. Mary's Hospital; on the staff of St. Joseph's Mercy Hospital, where he died May 21, aged 56, of heart disease.

Robert Taylor Wheeler ☉ Brooklyn; College of Physicians and Surgeons, New York, 1892; served on the staff of the Bethany Deaconess Hospital; June 5, aged 76, of cerebral hemorrhage.

LIEUT. FRANK REICHENBACH
(MC), U.S.N.R., 1909-1944

LIEUT. VICTOR HERBERT KARPASS
M. C., A. U. S., 1909-1942

CAPTAIN KARL MARTIN RAGUE
M. C., A. U. S., 1917-1945

Frederick Vail Thompson, Belmar, N. J.; Long Island College Hospital, Brooklyn, 1890; died in the New Jersey State Hospital, Marlboro, May 18, aged 78, of arteriosclerotic cardiovascular renal disease.

Waddy Thompson Wilkinson Jr., Coushatta, La.; University of Arkansas School of Medicine, Little Rock, 1931; interned at Missouri Pacific Hospital, Little Rock; died May 28, aged 42.

KILLED IN ACTION

Frank Reichenbach, Watertown, Conn.; Tufts College Medical School, Boston, 1933; member of the American Medical Association; on the associate surgical staff at the Waterbury Hospital, Waterbury, where he served an internship and a residency and where he took an active part in the tumor clinic, serving as chairman for two years; served a residency at the Westfield State Hospital in Westfield, Mass.; organized the outpatient follow-up tumor clinic at the Chase Memorial Dispensary and was instrumental in organizing a biopsy service in the Waterbury area; fellow of the American College of Surgeons; formerly health officer of Woodbury; began active duty as a lieutenant in the medical corps of the U. S. Naval Reserve on July 5, 1943; his first year was spent at Davisville and Newport, R. I., and Lido Beach, Long Island; in July 1944 left for overseas, where he was stationed in England and France; senior surgeon to the 114th Construction Battalion; killed in France Nov. 6, 1944, aged 35.

Victor Herbert Karpass, Chicago; University of Illinois College of Medicine, Chicago, 1935; member of the American Medical Association and the Missouri State Medical Association; interned at St. Mary's Hospital in Minneapolis and the Woodlawn Hospital in Chicago; served a residency at the Anna State Hospital in Anna, Ill.; began active duty as a first lieutenant in the medical corps, Army of the United States, on Feb. 24, 1942; awarded posthumously the Distinguished Service Cross for heroism; killed in action in Africa Nov. 8, 1942, aged 33.

Karl Martin Rague, Manchester, Mich.; University of Michigan Medical School, Ann Arbor, 1942; interned at the Robert Packer Hospital in Sayre, Pa.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 29, 1943; promoted to captain; mortally wounded at Bastogne, Belgium, on January 9; died at 101st Evacuation Hospital in Eastern France January 10, aged 27.

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *The Journal*. Following are brief abstracts of some fraud orders not dealt with previously:

Hema-Tone Laboratory and John B. Swabey, M.D., N.D.—From Muskegon, Mich., Dr. Swabey conducted a mail-order business under the title mentioned, selling certain preparations comprising his "New Natural Home Treatment," which he represented to overcome any disease of the prostate gland, regardless of the age of the user or chronicity of the condition, as well as kidney and bladder disorders, and to restore persons afflicted with "male weakness" to "manly strength." Further, he represented that he could correctly diagnose the physical condition of his mail-order inquirers and properly prescribe treatment on the basis of a urinalysis and replies submitted in a questionnaire which he sent out. Advertising was done in periodicals of national circulation and through written and printed matter sent through the mails. In this Dr. Swabey was claiming as recently as 1942: "It has become my privilege to teach and demonstrate my theory of regeneration of the prostate gland. . . . In April 1934 I published the first announcement in medical history, of a theory and plan of treatment designed to assist Nature in the process of regeneration of the prostate gland. . . . Prior to the above date mentioned, medical science had no adequate treatment to offer for the non-specific diseases of the uro-genital system. And so far as I know have nothing of scientific value to offer now. . . . These good and faithful doctors, leaders of the Medical Profession, and eminent teachers of Medical Practice, have admitted that Medical Practice, as we know it, is useless in such cases. This left an open field for my research work. . . ." After the Post Office Department had thoroughly investigated Dr. Swabey's activities, it notified him to be present at a hearing in November 1943 and show cause why his business should not be declared a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. He neither put in an appearance nor sent counsel to represent him. The testimony of a chemist and a physician, both appearing as witnesses for the government at the hearing, resulted in the recommendation that a fraud order be issued against the Hema-Tone Laboratory and John B. Swabey, M.D., N.D., and this was accordingly done. It is worth noting that a few weeks after the hearing Dr. Swabey died of a disorder of the prostate and bladder, the very organs for which his "treatment" was promoted.

Herb-Vite Company and Rite-Wate Company.—These were the names variously used by a New York concern that sold "Herb-Vite Tablets" and "Rite-Wate Tablets," which were identical in composition, according to the ingredients named on their respective labels, and which emanated from the same address. With the first-named product came a booklet presenting the "Herb-Vite Reducing Method." The names of the backers of this concern were not reported. The Post Office Department, after investigating the business, charged it with being a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. Among these were that the Herb-Vite Reducing Method would enable obese persons, including "difficult" cases, to eliminate their excess fat and attain a "slim" and "lovely" figure quickly, harmlessly, and without the necessity of a restricted diet; that the users could effect this reduction while still eating plenty of food; that the essential action of the Herb-Vite Tablets was soothing, non-habit-forming, absolutely harmless, and produced laxation without griping or irritation; and that persons using these tablets would obtain the same alleged beneficial results as those whose purported testimonials were set forth in the company's circulars. At the hearing of the case in November 1943, the respondents sent no one to represent them. A chemist for the Food and Drug Administration, appearing as a witness for the government, testified that the ingredients, as declared on the label—government, testified that the ingredients, as declared on the label—were colocynth, jalap, podophyllin, leptandrin, gentian and peppermint—were confirmed by his own examination, except that he found no peppermint present. Another witness for the government was a Senior Medical Officer of the Food and Drug Administration, who testified that he was familiar with the actions of the ingredients named, and that this mixture of irritant laxatives would not enable obese persons to eliminate their excess weight and obtain a slim figure quickly, harmlessly and without following a restricted dietary regimen. He also showed, among other things, that regardless of the laxative effect of the tablets, the user's weight would be practically the same if the quantity of food consumed was not materially reduced. Further, his testimony brought out that the drugs in question produce griping and irritation and, on continued use, a laxative habit, nor are they "absolutely harmless," as they would be dangerous in certain conditions, such as appendicitis, stomach ulcers, gallstones and other inflammatory disorders of the intestinal tract. At this hearing the further fact was emphasized that an inquiry addressed to the Herb-Vite Company had brought a reply from the Rite-Wate Company, and when an order was sent to the latter, it mailed the inquirer a box of "reducing tablets" bearing a formula and directions for use identical with those on the box of Herb-Vite Tablets. On May 4, 1944, the Post Office Department issued a fraud order against the Herb-Vite Company and the Rite-Wate Company at New York, debarring them from further use of the mails, on the ground that they had conducted a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises.

Mrs. Nancy Young.—From Alba, Texas, this person sold through the mails what she represented to be a cure for cancer, dropsy, pellagra, female diseases, rheumatism and kidney and bladder disorders. To one inquirer she wrote in part: "I treat everything that any one could suffer with Cancer & Pelagra Dropsy female trouble of all Kind Kidney & Bladder Trouble Rheumatism & in facts everything. . . . My Cancer Cure is Wonderful. . . . Hoping to hear from you Soon." Because of this obvious abuse of the mails and imposition on the public, the Post Office Department, after due investigation of the treatment and its promotion, notified Mrs. Young to show cause why a fraud order should not be issued against her. She neither put in an appearance at the hearing of the case held in Washington nor sent anyone to represent her. On this occasion a chemist and a microanalyst of the Food and Drug Administration, witnesses for the government, testified regarding their respective chemical and microscopic examinations of each of the packages of capsules and herbs sent out by Mrs. Young in response to two orders for her "cancer treatments." The witnesses showed that the two treatments purchased were essentially identical, each consisting of four separate packages. The first of these contained gelatin capsules in which were found podophyllum, powdered root bark and stems of dogwood. The second contained capsules of powdered podophyllum. The third and fourth were practically identical, consisting of fragments of root bark, stems of dogwood, and two species of mint, with small amounts of sodium and potassium oxides, iron, calcium, sulfate and chlorides. These were to be made into a solution, and accompanying each package were handwritten instructions on plain paper. Another government witness, a Senior Medical Officer of the Food and Drug Administration, testified that he was familiar with the modern scientific medical treatment of cancer and the other diseases played up by Mrs. Young; that a cancer is a malignant tumor which will in due time result in death unless scientifically treated by surgery, X-ray or radium, and that there is no known drug, herbal treatment or dietary measure which will cure the condition. Hence Mrs. Young's nostrums would be absolutely worthless in treating cancer. Accordingly, a fraud order was issued on Oct. 3, 1944, against Mrs. Nancy Young.

Correspondence

HEPATITIS FOLLOWING BLOOD OR PLASMA TRANSFUSION

To the Editor:—In the paper on "Hepatitis Following Blood or Plasma Transfusions" by Capt. E. M. Rappaport in the issue of July 28 it is stated that those blood donors in the preicteric stage or with hepatitis without obvious jaundice constitute the greatest menace as propagators of hepatitis. It is further stated that "in view of the widespread incidence of infectious hepatitis a transient healthy carrier state might exist among some volunteer blood donors and detection of such depositors would be impossible."

For the detection of those in the preicteric stage, the following suggestions were made: (1) "Recording the lot number of each flask of plasma at the time of its use, thus permitting ultimate withdrawal of contaminated batches"; (2) "that quantitative bilirubin determinations be performed routinely on all patients who have received plasma or blood from doubtful sources at monthly intervals from the third to the sixth month after transfusion."

It seems to me that a more effectual method would be to detect the possible source of jaundice before it has been allowed to operate by icterus index or van den Bergh tests on donors' blood rather than to seek to find the responsible lots of blood or plasma after cases of hepatitis have developed.

The icterus index is a simple test and entirely reliable when fasting blood is used. It is exceedingly rare for the icterus index to be above 6 in the normal subject in the fasting state. The raised index from carotenemia in the normal individual disappears in four to five hours after eating. Persistent carotenemia presumably indicates some liver dysfunction and is therefore abnormal. It may possibly occur in infectious hepatitis; accordingly, in this respect the icterus index, which measures the color of the serum only, may be a more suitable test than the van den Bergh reaction. The so-called physiologic hyperbilirubinemia is rare and may be considered negligible in this situation.

It is the practice of the Red Cross to give orange juice just before venipuncture. What effect, if any, this would have on the icterus index could be easily ascertained. Usually the

icterus index rises for a few hours after meals, in some cases 1 or 2 points. Thus a high normal reading of 6 may be 7.5 to 8 after eating. The zone of latent jaundice, or the preicteric stage, lies between 6 and 15 in the fasting state. Clinical jaundice appears with an icterus index of 15.

ALICE R. BERNHEIM, M.D., New York.

INFECTIOUS HEPATITIS

To the Editor:—In the article of Col. M. H. Barker, Major R. B. Capps and Major Frank W. Allen on infectious hepatitis (*THE JOURNAL* August 4, p. 997) the statement is made "The oral hippuric acid liver function test in our hands has shown practically no correlation with the clinical condition of the patient. Thus the test frequently gave relatively normal results during the acute stage and very low results in the convalescent period." This is rather surprising, since in my early studies of the test I found it consistently low in catarrhal jaundice, which many consider closely related to the entity. Recently Rennie (*Am. J. M. Sc.* 210:18 [July] 1945) in 39 cases of infective hepatitis found the output of hippuric acid much reduced in 27 during the acute stage. In many patients the test was run serially over a period of weeks, with strikingly consistent results. Rennie further found that when the plasma bilirubin was greater than 10 mg. per hundred cubic centimeters the hippuric acid synthesis and the levulose tolerance test were invariably impaired and the plasma albumin was below normal.

The fact that the hippuric acid as well as other tests are often low during the convalescent stage is of clinical significance especially in the prognosis and perhaps in establishing a criterion of complete recovery.

ARMAND J. QUICK, M.D., Milwaukee.

ALCOHOL AND PANCREATIC NECROSIS

To the Editor:—The editorial (May 12, p. 144) on "Intravenous Alcohol Anesthesia as Used in Russia" and other recent work (Moore, Daniel C., and Karp, Mary: *Intravenous Alcohol in the Surgical Patient, Surg., Gynec. & Obst.* 80:523 [May] 1945) suggest another revival of interest in alcohol as an anesthetic agent. It seems in order, therefore, to call attention again to a poorly understood and, in my opinion, not widely known relationship between alcohol and acute (as well as chronic) pancreatic necrosis (Weiner, H. A., and Tennant, Robert: A Statistical Study of Acute Hemorrhagic Pancreatitis, *Am. J. M. Sc.* 196:167 [Aug.] 1938). Statistically, the relationship is clearcut, though unimpressive in view of world alcohol consumption figures. Occasionally it is dramatic and unforgettable.

H. A. WEINER, M.D.

2d General Hospital, A. P. O. 513, New York.

LOEFFLER'S SYNDROME AFTER CUTANEOUS HELMINTHIASIS

To the Editor:—The report of Wright and Gold in *THE JOURNAL*, August 11, of Loeffler's syndrome following cutaneous helminthiasis adds a hitherto unreported etiologic factor and supports the view that this syndrome is an allergic phenomenon. For the sake of completeness, it is worthy of note that the first report of Loeffler's syndrome in the United States known to me indicated that the allergic response in the case observed (Ellis, Ralph V., and McKinlay, C. A.: *Allergic Pneumonia, J. Lab. & Clin. Med.* 26:1427 [June] 1941) was due to the oral administration of a sulfonamide compound.

C. A. MCKINLAY, M.D., Minneapolis.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of a "Duplicate" License Fraudulently Obtained to Replace a Nonexistent "Original" License.—Jacobson, a graduate of Middlesex College of Medicine and Surgery, obtained in 1936 from the Rhode Island Board of Examiners in Medicine a so-called "duplicate" certificate of authority to practice medicine to replace a certificate that he claimed had been issued to him on Oct. 11, 1934 by the state public health commission, which at that time had the authority to issue such certificates, after examination but which he had subsequently lost. Later the board instituted proceedings to revoke the duplicate certificate on the ground that it had been obtained by fraud, since no original certificate had ever been issued to him. After due notice and hearing the board ordered the so-called duplicate certificate revoked, and Jacobson appealed to the Supreme Court of Rhode Island, which in accordance with the applicable law heard the matter *de novo*.

Jacobson contended that the Supreme Court could not properly hear and decide the appeal because in the hearing before the board there was not a sufficient specification of the fraud with which he was charged to have been guilty in procuring the so-called duplicate certificate. The court, however, found no merit in the contention. The evidence, said the Supreme Court, discloses a chain of facts and circumstances which lead to the conclusion that Jacobson, through fraud or deception, obtained his certificate to practice medicine in Rhode Island. When the examinations to which Jacobson claimed he submitted and passed were conducted—Oct. 4 and 5, 1934—according to the rules of the department of public health, the medical college from which Jacobson graduated was not recognized as an approved college whose graduates were permitted to submit to examination, and there is no evidence that that requirement had been waived in favor of Jacobson to permit him to take the examination. There were introduced in evidence six manila envelopes, numbered 2193 to 2198 inclusive, taken from the files of the state department of health pertaining to the examination given on the dates referred to. None of the numbers on these envelopes is followed by a letter. There was introduced in evidence another envelop numbered "2197-A" which bore Jacobson's name and on the contents of which he relied as showing that he took and passed that examination and received a valid certificate. On each of the envelopes other than the one bearing Jacobson's name the number was shown in large heavy figures, bluish green, all of the same size, and plainly not typewritten. On the envelop bearing Jacobson's name the number is much smaller, with less heavy figures, and is plainly typewritten in black. To our minds, said the court, these facts strongly indicate that the envelop numbered 2197-A purporting to relate to Jacobson had not been filed before or at the time of the examination of Oct. 4 and 5, 1934 but had been filed at some time thereafter.

It is also noteworthy, continued the court, that in every one of these envelopes except the one bearing Jacobson's name there is a receipt from the state treasurer's office showing the payment, into the state treasury by the applicant for a license, of a \$20 examination fee, while no such receipt is among the papers in the envelop bearing Jacobson's name. The medical practice act in force at that time required any applicant presenting himself for examination to present to the board of examiners a receipt from the general treasurer that he had paid the required \$20. Jacobson testified that before taking the examination he paid \$20 to some unknown, unidentifiable employee in the office of the state board of health and that he received no receipt therefor. The physician who was director of public health during the period in question testified that the return of

such a receipt to the department of health was a prerequisite that was never waived and that he gave out the blank examination books only to applicants who showed receipts from the state treasurer. As further indicating that Jacobson never took or passed the examination in question, the physician just referred to testified that during his term of office it was the custom to give out in writing to certain newspapers, including the *Providence Journal*, the names of applicants who had passed the examination for certificates of authority for the practice of medicine and to check up on the names of those who were reported in these newspapers as having passed such examination and to call any error to the attention of the newspapers so that it could be corrected. A copy of the *Providence Journal* for Oct. 12, 1934 was then introduced in evidence containing a list of the names of nine persons who had successfully passed the examination of Oct. 4 and 5, 1934 and Jacobson's name was not in that list. Further, a physician who was a member of the state public health commission at the time of the examination in question testified that he gave the examination in one of the subjects and that Jacobson did not take that examination.

Jacobson's main reliance to prove that he had in fact been issued the original certificate in dispute was an exhibit containing certain papers enclosed in a manila envelop marked "State Cert. No. 2197-A Name Jacobson, Charles Date Issued 10-11-34." On the back of one of the documents contained in that envelop the following appeared: "State Certificate No. 2197-A. Issued October 11, 1934 Rhode Island State Public Health Commission . . . Application of Charles Jacobson Application received Sept. 3, 1934 Fee received for examination . . . 193. Appeared for examination Oct. 4, 1934 . . . Graduate from Middlesex 1932 Photograph received Sept. 3, 1934 Average per cent. obtained 81.5." These last figures had been put in with a lead pencil. In the envelop was also a so-called "application" in the same form as the applications that were filed in the other manila envelop referred to containing the applications and other papers of persons who admittedly passed the examination of Oct. 4 and 5, 1934 and who subsequently received licenses. The purported application of Jacobson showed, among other things, what purported to be a statement of the percentages at which his answers were rated by the examiners in the separate subjects. This statement bore the date "October 11, 1934." At the end of the document was an unframed photograph of Jacobson. On the first inside page of the purported application Middlesex College of Medicine and Surgery was written in as the medical college from which Jacobson was graduated and on the next line below appeared the date of graduation, written in ink, "June 15, 1932." But, said the court, an inspection of the writing showed that the letters "une" in June, the figure "5" in the "15" and the figure "2" in the "1932" had been written in after the erasure of previous letters and figures. The envelop also contained an original letter dated Feb. 26, 1937 from the registrar of Middlesex College to the division of examiners which, in part, said "Please be advised that Dr. Charles Jacobson was graduated with the degree of Doctor of Medicine from the Middlesex College of Medicine and Surgery on August 7, 1933." The purported application also included a jurat bearing the signature and seal of Greenspan, a notary public, and stating that the application was signed and sworn to before him on the "3d. day of Sept. A. D. 1934," the open space between the 3 and the 4 being large enough for another figure. Greenspan had first testified that he could not recollect the date on which he took this acknowledgment, and on request he wrote a figure 4 on a sheet of paper which he admitted was obviously different from the figure 4 that appeared in the jurat. Later in the course of the hearing the state toxicologist testified, as an expert in restoring erased handwriting, that he had a chemical which would restore erased writing if the ink used contained iron. He then applied this writing to the open space between the figures 3 and 4 in the year date in the jurat referred to and as a result a figure was brought into view which was clearly not a 4 and which was or very

closely resembled a figure 5 and which the witness testified had been removed by a chemical ink eradiator. Greenspan later testified that that figure looked like his 5 and that he had not used an ink eradiator to change the date he had written. Thus, concluded the court, the evidence as to the date of the jurat, even if considered alone, makes it extremely improbable that Jacobson's application was filed before the examination was given in October 1934.

Other evidence was discussed by the court tending to show that Jacobson in fact had never submitted to the examination in question nor received a certificate. There was, for instance, produced a photostatic copy of an application by Jacobson to the board of registration in medicine in Massachusetts in 1935 in which in response to a question as to states in which he was licensed to practice medicine he did not mention Rhode Island. The Supreme Court thought it extremely unlikely that he would not have answered Rhode Island in answer to that question if he had in fact received such a license. Again there was testimony from a physician who had been examined on Oct. 4 and 5, 1934 and who had been licensed thereafter that a short time before the hearing before the board Jacobson had asked him to testify that he of his own knowledge knew that Jacobson had taken the examination and that he informed Jacobson that he could not do so.

It seems obvious to us, continued the court, that some employee of the department of public health or some other person having knowledge of its methods and access to its records must have cooperated with Jacobson in preparing the papers on which he mainly relied and in causing the issuance to him of the so-called duplicate certificate, but there is no reason to go into that phase of the matter, as it is not necessary to do so to establish Jacobson's fraud. We find that the board of medical examiners proved by credible evidence that Jacobson did not take the examination of Oct. 4 and 5, 1934; that no original certificate was issued to him; and that such so-called "duplicate" certificate of authority to practice medicine was obtained by fraud and should be revoked. The order of the board revoking the duplicate certificate was accordingly affirmed. —*Board of Examiners in Medicine v. Jacobson*, 42 A. (2d) 887 (R. I., 1945).

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Jan. 18. Final date for filing application is Oct. 20. *Oral*. Various centers, Oct. 1946. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 24.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, May 27. Final date for filing application is Feb. 1. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Various centers, Feb. 2. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Jan. 18-22 and Los Angeles, Jan. 28-Feb. 1. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6 (canceled). Spring 1946. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written*. Locally, Oct. 19. *Oral*. New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY. *Written*. Part I. Spring 1946. Final date for filing application is Dec. 1. Sec., Dr. J. Stewart Rodman, 225 South 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*. Various centers, Dec. 9. *Oral*. Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Subacute Bacterial Endocarditis in the Aged.—A review of 700 postmortem examinations of persons aged 60 years and over revealed a surprisingly high incidence of acute and subacute bacterial endocarditis. There were 18 cases of subacute bacterial endocarditis in the age range 60 to 87 observed in the wards of the Mount Sinai Hospital during the past ten years. Zeman emphasizes the high incidence of rheumatic valvular lesions as the basis for the endocarditis, with the occurrence in this role less frequently and in the order named of arteriosclerotic, syphilitic, congenital and thyrotoxic heart disease. Approximately one half of the cases exhibited a typical, though often modified, clinical picture. A group of more difficult cases may be subdivided into bacteria free cases, characterized predominantly by heart failure, splenomegaly, anemia and renal insufficiency, and into cases which completely elude precise diagnosis owing to the masking of the endocarditis by involvement of the central nervous system and by a variety of other clinical findings which tend to distort diagnostic emphasis. Clinical recognition of subacute bacterial endocarditis depends on the physician's constant effort to achieve diagnostic accuracy in the aged by utilizing for them the same careful observation and the same methods of precision commonly employed for the young.

Lesions of Left Atrial Endocardium in Chronic Rheumatic Heart Disease.—Sections of the left atrium were obtained from 100 nonrheumatic and 100 rheumatic hearts. The rheumatic hearts were the seat of chronic or healed disease and showed no active gross lesions. Seventy-five showed mitral stenosis and 25 had nondeforming mitral valvulitis. In the 100 hearts with chronic rheumatic disease there was gross involvement of the left atrial endocardium in 42 cases and microscopic involvement in 60 cases. Certain microscopic lesions of the endocardium of the left atrium, which occur rarely if at all in normal hearts or in other types of heart disease, form practically pathognomonic stigmas of rheumatic endocarditis. In the endocardium proper these include vascular penetration, cellular exudate and cellular hyperplasia of connective tissue; in the subendocardium they include excessive vascularity and cellu-

lar exudate, the presence of small arteries with musculoelastic wall and Aschoff nodules. Other lesions, such as subendothelial plaque, endocardial fibrosis and increase in thickness of smooth muscle, may be highly suggestive of rheumatic disease but require differentiation from corresponding alterations in structure of the normal endocardium. Rheumatic endocarditis of the left atrium usually occurs in hearts with deformity of the mitral valve and with more or less widely distributed microscopic rheumatic stigmas, especially of the valves. In occasional instances, however, atrial stigmas aid in establishing rheumatic fever as the cause of equivocal valvular disease.

Fatty Hepatomegaly with Pancreatic Fibrosis Controlled by Lipocaic.—For the past eighteen months Browne and Thomas have observed a patient who exhibits many of the signs and symptoms of lipocaic deficiency. The administration of lipocaic, furnished by Dr. Dragstedt's laboratory, has produced a striking decrease in the size of the enlarged liver, stabilized the fat concentration of the blood and improved the liver function. There was gain in weight, restoration of appetite and a sense of well-being. The withdrawal of lipocaic has repeatedly caused the reestablishment of the syndrome. The appearance of pronounced fatty infiltration of the liver in this patient together with evidence of extensive fibrosis of the pancreas as revealed at the exploratory operation suggests an interrelationship between the two phenomena. Exacerbation of the hepatomegaly due to the ingestion of large amounts of alcohol, which occurred several times in this case, is interesting in view of Connor's observations that fatty infiltration of the liver represents an early stage in the development of cirrhosis. The complete recession of the hepatomegaly and striking clinical improvement produced by the administration of lipocaic presents evidence that a deficiency of this secretion due to the fibrosis of the pancreas was the underlying cause of the disease.

Aerosinusitis.—According to Schneider, aerosinusitis is a dramatic disorder of the paranasal sinuses characterized by traumatic, sudden, severe pain localized over the affected sinuses and occurring during descent from altitude in an aircraft or altitude chamber. Its immediate cause is apparently sudden obstruction of a sinus ostium, as by a mucous plug or loose mucosal membrane, thereby sharply and radically increasing the relatively negative intrasinus pressure which presumably exists already in the sinus during descent. The intense pain of this condition is attributed to sudden ballooning of the sinus mucoperiosteum induced by the great negative pressure. Edema and transudation in the sinus may occur and may be accompanied by hematoma and/or frank hemorrhage. The x-ray appearance and the history are characteristic in this disorder. It is also possible that the pressure gradient may lead to an infective sinusitis by forcing aspiration of infected nasal secretions into a sinus previously damaged by infection.

Calcified and Bony Nodules in Lungs Associated with Mitral Disease.—Grishman and Kane draw attention to the coexistence of disseminated calcified and bony lesions in the lungs and rheumatic mitral disease. The present report is an attempt to correlate the x-ray, pathologic and clinical findings in 8 cases. The lesion was discovered in 4 cases preceding the first episode of congestive heart failure. The pathogenesis of the pulmonary lesions is not clear. There is no microscopic evidence that pulmonary arteritis or small pulmonary infarctions are precursors of such lesions. They suggest that careful inspection of the lungs in cases of adolescent or preadolescent rheumatic fever may yield significant data. The clinical histories of the reported cases suggest strongly that the precursor to these lesions must appear early in rheumatic fever and probably in childhood. The triad of symptoms that is important in the differentiation from tuberculosis is (1) the predominantly basal bilateral distribution, (2) the association with evidence of mitral stenosis and (3) the absence of other evidence of pulmonary tuberculosis.

Picrotoxin in Barbiturate Poisoning.—Burdick and Rovenstine maintain that from the point of view of safety and sustained effectiveness picrotoxin is preferable to other analeptics in the treatment of barbiturate poisoning. Mortality rates of over 7 per cent have been reported in attempted suicides with barbiturates. Prolonged hypoxia, intercurrent pulmonary infection, pulmonary edema, cerebral edema, nutritional deficiencies, depressed kidney function, decubitus ulcers and transient or

more permanent neurologic sequelae are frequent accompaniments of prolonged barbiturate narcosis and should be avoided if possible. The authors think that to those familiar with its action and the method of administration there is no reason to withhold picrotoxin from patients for whom its use is indicated. It should be employed early and in adequate amounts supplemented by other, supportive measures. Four essentially similar cases are presented to illustrate the effects of neglected, inadequate, delayed and more immediate treatment. Early and adequate analeptic therapy with picrotoxin may prevent death, obviate a prolonged illness and result in a complete or more nearly complete recovery.

Esophageal Obstruction.—Richardson reports 17 cases of esophageal obstruction due to meat impaction. Only 2 adults and a 6 year old child had good teeth: each of these 3 had a strictured esophagus. Two other adults had teeth of their own, but 1 had many teeth missing and the other had broken teeth and many infected roots. The remaining 12 patients had no teeth of their own. The upper plate was blamed by them as the cause of their mishap. The upper artificial denture takes away the ability to feel food between the tongue and the hard palate. Consequently an overly large bolus of the food may pass back to the soft palate and be swallowed sooner than the victim intends. Six of the 17 persons had a normal esophagus. The other 11 had a narrowing or constriction of some portion of the esophagus. If the patient is young, nervous and without esophageal narrowing, morphine sometimes relaxes the normal esophagus sufficiently so that the foreign body slides down into the stomach. Spontaneous recovery can occur but is rare. Heretofore the esophagoscope has usually been employed for removal of the foreign body, particularly if the patient has waited several days before seeking help. Drew had successfully used caroid to dissolve impacted meat. Richardson used it or its chief constituent, papain. The proteolytic enzyme papain was orally ingested in a 5 per cent solution. Sixteen of these patients were promptly relieved of their obstruction. One patient, unable to retain the medicine, required operative removal of the foreign body. Operative removal of meat causing esophageal obstruction will seldom be necessary if the patient is given orally the proteolytic enzyme papain.

Penicillin in Subacute Bacterial Endocarditis.—Bloomfield and his associates administered penicillin alone to 11 patients with subacute bacterial endocarditis. These patients had positive blood cultures; their strains of nonhemolytic streptococci were sensitive to penicillin in the test tube; their condition was not desperate and they agreed to stay in the hospital for from six to eight weeks. They were given from 200,000 to 500,000 units in twenty-four hours by continuous intravenous drip for three weeks and thereafter 120,000 to 200,000 units

per day in eight intramuscular injections (5,000 units per cubic centimeter of isotonic solution of sodium chloride) for three to five weeks. Most of the patients were treated for eight weeks without interruption. All patients were promptly made "bacteria free" except 1 who died early in the course of treatment. Eight were clinically cured of the infection after follow-up periods up to six months. One patient, apparently cured of the infection, died of cardiac failure. Cocci were seen in the depths of a scarred mitral valve. There were no clinical relapses or reinfections. Petechiae and emboli continued for some time after the blood cultures were negative. Renal lesions as evidenced by studies of urinary sediment were not as a rule completely eliminated by the treatment.

Sulfamerazine in Meningococcic Meningitis.—Reinhold and his associates evaluate the response of patients suffering from meningococcic meningitis to treatment with sulfamerazine, with particular reference to the concentration of this substance in body fluids. The comparative significance of drug concentrations in plasma, plasma ultrafiltrate and cerebrospinal fluid also has been examined together with the distribution of sulfamerazine between these fluids. The results of treatment of meningococcic meningitis with sulfamerazine were studied in 188 patients at the Philadelphia General Hospital. It was found that the concentration of sulfamerazine in cerebrospinal fluid is approximately 80 per cent of that of an ultrafiltrate of plasma and is closely dependent on the same factors governing the concentration of the drug in the ultrafiltrate, i. e. concentrations of drug and protein in plasma, and composition of the protein. In meningococcic meningitis higher concentrations of sulfamerazine in body fluids were associated with more rapid return of body temperatures to normal, more rapid disappearance of meningitic irritation and more rapid decrease in cerebrospinal fluid protein concentrations than were lower concentrations. For each milligram of increase in plasma sulfamerazine concentration the average response was shortened by one day. The results suggest that the dosage in common use is suboptimal and that further trials with therapeutic concentrations in blood serum above 20 mg. per hundred cubic centimeters are needed. Determinations of concentrations of sulfamerazine in cerebrospinal fluid or plasma ultrafiltrates offer no advantage in evaluation of therapeutic response in meningococcic meningitis over such determinations in plasma. Certain toxic manifestations (drug fever) of sulfamerazine appear to be more frequent at higher concentrations of drug in plasma. Others (rash, hematuria) showed no such relationship. The incidence of toxic manifestations increased appreciably after one week of treatment, reaching a maximum about ten days after treatment was started.

Penicillin in Pneumococcal Pneumonia.—Meads and his associates report the results of treatment with penicillin in a series of 54 cases of pneumococcal pneumonia. Penicillin was used alone in 37 of these cases, whereas in the remaining 17 cases it was given only after sulfonamide drugs had either failed to bring about a satisfactory response or produced untoward effects. Intermittent intramuscular administration of penicillin was the most feasible method and was generally used. Most of the patients with moderately severe symptoms were given from two to six injections of 15,000 units every two hours, and then the same amount was given every three hours until there was clinical improvement and the temperature had remained below 100 F. for twelve hours. Additional doses of 10,000 units each were then given every three hours for another two or three days. In the severe cases the same general scheme of dosage was used except that a single dose of 5,000 or 10,000 units was given intravenously in some cases at the time of the first intramuscular injection and from six to twelve injections of 15,000 units were given at two hour intervals. The average total dose varied between 317,000 and 735,000 units. Bacteremia cleared rapidly. Fever and acute symptoms subsided in most cases within twenty-four to forty-eight hours. Subjective improvement often preceded the drop in temperature. There were ten deaths. Seven of these were of patients who were moribund at the time treatment was begun; the other three deaths were associated with severe complicating conditions. Purulent complications did not develop following penicillin therapy. Penicillin was equally effective in cases in which it was used alone and in those which had previously failed to respond to sulfonamides.

Listerellosis.—According to Kaplan listerellosis is a sporadic, infectious disease occurring naturally in man and in animals, including cattle, sheep, goats, swine, foxes, chickens, rabbits, guinea pigs, gerbils and rats. The causative organism, *Listerella monocytogenes*, was first submitted as a new species (*Bacterium monocytogenes*) in 1924 by Murray, Webb and Swann, who isolated it from an epizootic affecting their laboratory rabbits and guinea pigs. In 1929 Nyfeldt recovered the organism from the blood stream of a youth aged 17 with infectious mononucleosis. It is highly probable that the diphtheroid organisms isolated from cases of meningitis in 1915 by Atkinson and in 1919 by Dick were *Listerella*. There have been reported in the literature 23 definitely diagnosed and 13 probable cases of human listerellosis. In its typical meningeal form the disease had a mortality of approximately 79 per cent. The natural habitat and port of entry of *Listerella monocytogenes*—other than transplacental infection in the newborn—are unknown. The nasal and gastrointestinal tracts appear as the likeliest routes of penetration. The facts that infection of the newborn can occur with no effect on the parent, that a *Listerella* bacteremia may be present in cases of infectious mononucleosis and that certain predisposing factors apparently produce active infection suggest that latent carriers play a significant role in the pathogenesis of listerellosis. At present there is little evidence to incriminate animals as direct transmitting agents of *Listerella monocytogenes* to human beings. The widespread prevalence of listerellosis in animals establishes them as possible reservoirs of infection for man. It is believed that the organism acts as a contingent invader in infectious mononucleo-

sis rather than as an incitant of the disease. Circumstantial evidence is cited supporting the possibility of interhuman communicability in active cases of listerellosis, thus making advisable the practice of communicable disease precautions whenever this disease is encountered. Clinically and at necropsy listerellosis is characterized by a meningoencephalitic syndrome. The most usual spinal fluid changes were increased pressure, globulin and leukocytes. A moderate neurocytosis occurred early in the disease. Treatment with sulfonamides appears to have been successful.

Sinusitis as Cause of Chronic Cough in Children. J. R. Bowman.—p. 215.

Landry's Paralysis Following Antirabies Vaccine.—Simple abrasions and scratches should be cleansed with soap and water, iodine and alcohol or with mercury bichloride. Cauterization is ineffective unless used within an hour after injury, and then it destroys only the virus remaining on the surface. The use of the cautery does not lessen the mortality but is thought to prolong the incubation period and for this reason is considered to be of value. Pure phenol destroys virus rapidly. Vaccine should be given following a bite if the animal dies or develops rabies within ten days; also if it disappears or is a stray. Because of the extremely short period of incubation in injury of the face, lips, head and hands, and in deep multiple lacerations, it is advisable to give vaccine immediately and in large amounts. It has been estimated that about 3 in 10,000 patients receiving this treatment develop some sort of paralysis. The commonest form of paralysis, except the very mild ones, is one which resembles the ascending type described by Landry. The author observed this type of paralysis in a man who stated that after the second injection of rabies vaccine he felt "hot all over," but he had no other symptoms until after the last injection, when paralysis was rapidly progressing, so that within three days he was unable to move his hands or feet, and in four days the arms and legs could not be moved nor could he raise his head. There was some muscle soreness in both upper and lower extremities but otherwise no sensory changes. He was admitted to the hospital. Hot compresses were applied and vitamins E and B₁ were given. From 100 to 300 mg. of thiamine was given daily, both the oral and intravenous routes being used. Wheat germ oil was given orally for the first three weeks. For about three weeks the case seemed hopeless. The patient began to be able to detect a little movement in the big toe on the right and then the muscles of his neck became stronger, then the muscles of his back, and after eight or nine weeks he was able to sit alone. He was given daily hydrotherapy treatment, massages and so on for about two months. His progress has been slow but steady. He can now walk without crutches and can hold light things in his hands. At present he is taking 30 mg. of thiamine daily and swimming three or four times a week. In the past month he has been able to take a light job. Perhaps he is one of a group who would have got well eventually, regardless of what was done, even though he was getting steadily worse until treatment was instituted.

Electrical Diagnosis of Peripheral Nerve Injury.—

Ritchie describes measurements carried out in patients with nerve injuries. Four sets of measurements were recorded from each case. These were (1) the strength-duration relationship of threshold electrical stimuli (which include chronaxia figures), (2) the condenser capacities necessary for excitation in the technic of Cluzet (1905) and of Lewis Jones (1912), (3) the accommodation constants of the muscle during regeneration, as measured by progressive currents, and (4) the thresholds of excitability of the nerve-muscle complex to alternating currents of varying frequency. Characteristic quantitative differences are observed in the excitability of normal and of denervated muscle; during reinnervation intermediate values are detectable. Improvement of excitability appears a short time before the earliest sign of recovery detectable by purely clinical means, and this effect is of value in prognosis. The differences in absolute value of strength-duration figures obtained by different methods make the current-voltage relationships in living tissues of great importance in quantitative stimulation measurements; on account of the reactance of the tissues, stimuli of definite shape applied at the electrodes give rise to very different potential gradients across the actual excitable region.

*Low Blood Pressure. J. G. M. Hamilton.—p. 166.

Diagnosis and Description of Cancer. W. F. Harvey.—p. 181.

Low Blood Pressure.—Hamilton says that 90 mm. should be regarded as the lower limit of normal rather than the more commonly accepted figure of 110 mm. Systolic blood pressure in the range 90 to 110 mm. is frequently found in normal persons at all ages and is compatible with long life, good health and a high degree of physical efficiency. Adults possessing blood pressures in this range are unlikely to develop essential hypertension. Poor vasomotor control and systolic blood pressure of 90 to 110 mm. do not necessarily occur together. The

symptoms of persistent fatigue, dizziness and fainting attacks are not due to persistent hypotension, being frequently found in association with "normal" or elevated blood pressure. These symptoms are frequently due to psychoneurosis. He examined records of 53 patients whose predominant complaints were prolonged fatigue, lassitude, fainting turns, "blackouts," dyspnea and dyspepsia in explanation of which no organic lesion could be demonstrated and of which emotional disturbance was held to be the cause. Six had systolic blood pressures of 110 mm. or less; 13 had diastolic pressures of 70 mm. or less; 11 had diastolic pressures of 90 to 105 mm. With certain exceptions such as coronary thrombosis, paroxysmal tachycardia, cardiac tamponade and aortic stenosis, hypertension is not an expression of heart disease. Attempts to raise the blood pressure are usually unavailing and misguided as far as relieving the symptoms is concerned. When symptomatic benefit occurs, it is usually temporary. In view of the normal day to day fluctuations in blood pressure an increase of 5 to 10 mm. in the systolic pressure, sometimes hailed with joy as indicating successful therapy, cannot be regarded as of any significance. It is notable in psychoneurotic patients with blood pressure of 90 to 110 mm. that, at such times as the anxiety or other underlying emotional disturbance is less evident, not only are the general symptoms relieved but the blood pressure reading may be somewhat higher. Conversely, when the emotional disturbance again becomes prominent, the blood pressure may gradually fall to the lower levels. Postural or orthostatic hypotension is characterized by the occurrence of faintness or loss of consciousness on rising from the recumbent to the erect posture. Bradbury and Eggleston first described this disorder and gave details of 3 cases in which the blood pressures fell sharply from normal or elevated levels in the recumbent position to pressures of the order of 40 to 50 mm. systolic and 25 to 40 mm. diastolic in the erect position with loss of consciousness. It is usually considered that postural hypotension is due to a failure of splanchnic vasoconstriction to offset the gravitational effects of the assumption of the erect posture.

Penicillin by Inhalation.—In their experiments with the inhalation of penicillin Mutch and Rewell adopted the method of administration which had been standardized for sulfonamides. Mists were produced by a nebulizer actuated by oxygen pressure and delivered along wide streamlined conduits to a closely fitting nose piece detached from an oxygen unit. The subject was instructed to breathe out through the mouth, the lips serving as an outlet valve. The objective was to secure maximum deposition of mist on the respiratory mucous surfaces. Five healthy young men were selected for the survey. A preliminary trial was made in each case with the easily visible mist formed from 2 per cent glycerin in water and the rate of oxygen flow

was adjusted to the person's minimal requirements. The penicillin solution was then switched in to replace the glycerin for thirty minutes. Samples of blood and urine were collected and the penicillin contents estimated. The strength of the residual solution left in the nebulizer was also estimated to ascertain whether half an hour's intimate exposure to pure oxygen at a temperature a little above zero had caused undesirable destruction of the drug. The volume of solution nebulized varied from 2 to 4.1 cc. It was found that calcium penicillin administered as a mist is rapidly absorbed through the respiratory mucous membrane. Highly bacteriostatic titers can be established in the blood in this way. The wastage of materials involved is 60 to 75 per cent, but the high values obtained in blood and urine encourage the hope that weaker solutions than those employed in this preliminary assay—e. g., 5,000 units per cubic centimeter or even less—could be used economically and successfully for the local treatment of infections of the respiratory mucosa and immediately adjacent tissues, such as purulent bronchitis and bronchiectasis and as a prophylactic against secondary pyococcic infections in influenza.

Action of Penicillin on Staphylococci.—Chain and Duthie attempted to demonstrate the bactericidal action of penicillin manometrically by its effect on the oxygen uptake of growing staphylococcus cultures. The manometric measurements were complemented by photoelectric turbidity measurements, hemocytometer counts and viability counts. It was found that during the "resting" phase even larger concentrations of penicillin have no effect on the oxygen uptake. During the early lag phase and the logarithmic phase of multiplication penicillin exerts a strong inhibitory effect on and eventually completely stops the oxygen uptake of the suspensions in very small concentrations (0.04 to 0.1 unit per cubic centimeter). The effect is not immediate but sets in after an induction period. Hemocytometer and viability counts, run parallel with the measurement of oxygen uptake, show that penicillin has a strong bactericidal effect on staphylococcus suspensions in the early lag phase and the logarithmic phase of multiplication but no measurable bactericidal effect during the resting phase. The observation of Hobby, Meyer and Chaffee that penicillin kills bacteria in nutrient mediums but has no bactericidal action on resting bacteria has thus been fully confirmed. When penicillin is added to a suspension of 200 million staphylococci per cubic centimeter in a nutrient medium during the early lag phase the turbidity increases about twofold during the first hour of the incubation but the total number of organisms remains constant. The increase of turbidity under these conditions is attributed to swelling of the organisms. Penicillin is capable of exerting a bactericidal effect on the staphylococcus before actual cell division has occurred. On the other hand, staphylococcus suspensions can go through at least one division in the presence of penicillin when it is added during the logarithmic phase of multiplication. Penicillin appears to interfere with a metabolic function in the early stages of bacterial development. Helvolic acid, the bacteriostatic antibiotic, antagonizes the bacteriostatic and bacteriolytic effects of penicillin on the staphylococcus. Sulfanilamide and sulfamezathine, which do not prevent the occurrence of at least several cell divisions, have no antagonistic action on the bactericidal effect of penicillin on the staphylococcus (and the streptococcus) but have, on the contrary, a synergistic effect. This effect is strong with naturally occurring penicillin resistant strains of staphylococci.

*Rat Leprosy: Observations and Transmission. J. W. Fielding.—p. 473.
*Infiltration with "Monacrin" (5-Aminoacridine Hydrochloride) as Alternative to Excision in Treatment of Contaminated Wounds. F. Arden.—p. 486.

*Rat Leprosy.—According to Fielding the geographic distribution of leprosy in rodent species is spreading. In New South Wales it has been detected in 2 specimens of *Mus musculus* and in 3 of *Rattus norvegicus*. The distribution of the

leprosy organisms in the body of infested animals is found to be the more generalized the more thorough the search. The author noted involvement of the stomach, pylorus, duodenum, sternum, pericardium, brain and bulbourethral and preputial glands. The lepra cells associated with the superficial lesions of the rat are considered to arise from the polymorphonuclear leukocytes, the nuclear structure of which is particularly or completely destroyed as the invading organisms increase in number. The virulence is much greater in the organisms from feces, urine and primary ulcers than in those from granulomas and old ulcers. It is suggested that by the passage of organisms from granulomas and old ulcers through guinea pigs and rabbits the virulence may be considerably built up. By superinfection at regular intervals with the virulent type of organisms, resistance may be broken down; however, superinfection with less virulent organisms tends to build up an immunity which eventually may destroy all signs of infection. Primary lesions of a temporary character are produced by subcutaneous injection of emulsions containing rat leprosy organisms. Lesions of a permanent character and primary in origin may be produced by repeated inunction with virulent organisms. Glandular infection is an early manifestation of the disease and may result from a single invasion of the organism through the skin. The musculocutaneous disease is a product of superinfection with more virulent organisms, producing lesions and intracellular organisms which are permanent features resulting in generalized infections. Even after organisms have been dry for twelve to eighteen months in the feces, infection may still be produced. Infection of rats has been effected by hookworm larvae, by feeding the lice and by inoculation and inunction of emulsions of ectoparasites. From the experience described, the early appearance of typical clinical lesions and the intracellularity of the organisms appear to settle the question of specificity of the acid fast organisms for leprosy.

Study of Infiltration with 5-Aminoacridine Hydrochloride Instead of Excision.—Arden studied accident cases at the Brisbane Children's Hospital to determine the efficacy of infiltration with 5-aminoacridine hydrochloride in preventing infection in contaminated wounds. After the patient was anesthetized, gauze swabs soaked in a 1:1,000 solution of 5-aminoacridine hydrochloride (in 0.45 per cent solution of sodium chloride) were placed in the wound while the surrounding skin was cleansed with a solution of zephiran concentrate. The wound was cleansed with the aforementioned gauze swabs. Fragments of tissue that had become separated from their blood supply were detached, but tissue which was merely bruised or lacerated was not removed and no general excision was undertaken. The margins and floor of the wound were then carefully infiltrated with the 1:1,000 solution of 5-aminoacridine hydrochloride. This preparation is a powerful bacteriostatic agent capable of inhibiting the growth of a wide variety of pathogenic organisms. A series of injections was made beneath the skin around the perimeter of the wound, about 1 centimeter apart. The subcutaneous tissues, muscles and other structures were then infiltrated in turn. In cases of compound fractures, solution was injected between the fractured ends. The wound was then closed in layers. The amount of solution varied between 1 and 30 cc. in the reported series of 16 cases. One pyocyanus infection developed; in 3 cases some aseptic necrosis of the skin resulted from the nature of the accident. The remaining 11 healed by first intention.

Hereditary Polyfibromatosis.—Touraine and Ruel apply the term hereditary polyfibromatosis to a hereditary constitutional condition in which the patients have a tendency to form nodular fibrous infiltrations, often multiple, in various parts of the body. This concept is not new, since Janssen in 1902

grouped under the term "fibroplastic diathesis" Dupuytren's contracture, induration of the corpora cavernosa, keloids, gout and arthritis deformans. Numerous more recent observations permit the enlargement of this picture and the incorporation in it of a long series of connective tissue hyperplasias and also the introduction of the role of heredity. The clinical characteristics of polyfibromatosis are the slow, progressive, insidious development, without apparent cause, of painless nodules of firm and hard consistency. Anatomically, polyfibromatosis is a fibrous hyperplasia of the connective tissue in the form of nodules, without enveloping capsule, formed of bundles of thick collagenic fibers. There may be local calcium deposits in the fibroid tissue. While the pathogenesis remains obscure, it seems that the process is one of progressive involution of the connective tissue toward sclerosis in the more general framework of abiostrophy. The genetic characteristics are those of simple, dominant heredity, with slight predominance for the male sex. The authors point out that polyfibromatosis is a new example of "polyphenic" heredity; that is, there are "ensembles" of fibrous hyperplasias the elements of which are transmitted either in identical sites, in different sites or in groupings. After classifying the fibromatoses into the peripheral, skeletal, visceral, vascular and metabolic forms, the authors discuss the grouping of the fibromatous conditions. They found 140 cases of such groupings. Dupuytren's contracture is often associated with the simultaneous retraction of the plantar and palmar aponeuroses or with induration of the corpora cavernosa. The association of the latter condition with Dupuytren's disease was found 30 times in the 140 cases. Aside from its combination with Dupuytren's contracture, induration of the corpora cavernosa has been found associated with keloids, fibromas of the fingers, osteopoikilosis, hypercalcemia and the like. Numerous other groupings of fibromatous conditions are cited.

Pulmonary Tuberculosis in School Children. M. Neira Salgado.—p. 123.

*Vaginal Smears of Newborn Infants. A. Guzmán and J. P. Franco.—p. 159.

Vaginal Smears of Newborn Infants.—Guzmán and Franco observed in 200 vaginal smears of newborn infants and in cadavers of newborn infants that the cytology of the vaginal mucosa resembles that of adult normal women in the premenstrual days. The smears show cells of the superficial and intermediate layers of the epithelium in a proportion of 20 of the former for each 5 of the latter. Cells of the deep layer of the epithelium, leukocytes and Döderlein bacilli do not appear in the smears for the first two weeks of life. The number of cells of the superficial layer of the epithelium progressively diminishes during the first week of life. The cells disappear after the twelfth day. A hyperestrogenic vaginal smear of the type of a pregnant woman was seen by the authors only in the vaginal smears of the cadaver of an infant with erythroblastosis fetalis. Smears of infants show atrophy of the vaginal epithelium from the second week of life up to puberty. When

vaginal smears of little girls and adolescents are of the type of normal adult women, they suggest either a hormonal pathologic condition or the effect of the administration of estrogens, as is the case when girls are given estrogenic substance for gonorrheal vulvovaginitis.

Poliomyelitis in Quito: First Epidemic Outbreak. C. Andrade Marin.—p. 177.

*Rat Bite Fever: Case. E. Cienfuegos and R. Montero S.—p. 186.

Rat Bite Fever.—Cienfuegos and Montero S. report that a normal infant at the age of 1 month was bitten by a black rat. The wound bled profusely. Iodine was applied to the wound three hours later. The infant showed symptoms of an acute infection, rigidity of the neck and profuse sweating eighteen hours later. The symptoms which followed were typical of Haverhill fever (epidemic erythema arthriticum). Streptococcus moniliformis was identified from the pus of an abscess which developed in the course of the disease. Sulfathiazole was ineffective. Repeated blood transfusions, vitamins and acetarsone (paroxil) in doses of 0.03 Gm. for each kilogram of body weight constituted the treatment. X-ray examinations of the limbs showed acute osteochondritis and periostitis, which are presumably responsible for the arthritic symptoms and which parallel the course of the fever. Complete recalcification of the epiphyses of the bones gradually takes place after subsidence of fever.

*Pernicious Anemia in Senile Age. C. R. Agustoni and A. L. Sansusti.—p. 799.

Penicillin in Gonorrhea: Cases in Santiago del Estero. L. G. Cortigiani.—p. 802.

Pernicious Anemia in the Aged.—Agustoni and Sansusti direct attention to the importance of pernicious anemia in the aged for the diagnosis and early therapy. The subjects of the authors' report were 3 women between the ages of 82 and 87 years. The early symptoms in all were the appearance of moderate pallor, lack of appetite, gastrointestinal disorders, acute edema about the ankles, depression or delirium. The hemogram was typical of pernicious anemia in all cases. The therapy consisted of liver extract in large doses and of hydrochloric acid. All patients recovered. The mental disorders were permanently controlled.

Surgical Care for Gunshot Wounds of Brain. W. Tönnis.—p. 275.

Operative Therapy and Prognosis in Fracture of Patella. E. Moberg.—p. 295.

*"Bone Chip" Grafts in Defects in Long Bones: Study on Transplantation of Bone Chips from Compact and Spongy Substance in Defects in Long Bones and Role of Periosteum and Endosteum in Bone Grafts from Compact Substance. A. Hellstadius.—p. 317.

*Surgical Treatment of Acute Hepatitis (So-Called Catarrhal Icterus). E. Bergenfeldt.—p. 329.

Pylonephritis Xanthomatosa. S. Osterlind.—p. 369.

Surgical Treatment of Acute Hepatitis.—Bergenfeldt describes 4 cases of acute hepatitis in which jaundice had persisted for seven months, two months, six weeks and five weeks respectively. Jaundice disappeared and the patients recovered rapidly after operation, which consisted in perfusion of the biliary passages with contrast medium and in 1 case with isotonic solution of sodium chloride as well. Bergenfeldt thinks that operation is indicated for patients with uncertain diagnosis, in whom biliary obstruction cannot be ruled out and for patients with hepatitis and severe icterus which does not diminish within a reasonable time and when there is danger of acute yellow atrophy and cirrhosis of the liver. Active surgical therapy can save a number of these patients. Perfusion of the biliary passages in the form of cholangiography should be tried first, because this must be done anyway to confirm the diagnosis. If this does not have the desired effect, a fistula can be made into the gallbladder.

Book Notices

Mass Radiography of the Chest. By Herman E. Hilleboe, M.D., Medical Director, Chief, Tuberculosis Control Division, United States Public Health Service, and Russell H. Morgan, M.D., Surgeon (R), Medical Officer-in-Charge, Radiology Section, Tuberculosis Control Division, United States Public Health Service. Cloth. Price, \$3.50. Pp. 288, with 93 illustrations. Chicago: Year Book Publishers, Inc., 1945.

Several books have been published on mass radiography in other nations, such as "Mass Miniature Radiography" by Trail and others, published by J. and A. Churchill Ltd., London, 1943, and "Mass Miniature Radiography of Civilians" by Clark and others, published by His Majesty's Stationery Office, London, 1945. However, this is the first book to be published on the subject in the United States. It is indeed fortunate that this first volume was written by physicians who have had wide experience in tuberculosis work and in the fundamentals of radiography, since at this particular time the value of the x-rays in the diagnosis of tuberculosis is greatly exaggerated, even to the point of making final diagnoses with no evidence whatever except shadows seen on x-ray films.

The limitations of the x-rays are numerous in the diagnosis of chest diseases. Therefore the public and even the medical profession could have been led far astray had such a book been prepared by authors not well grounded in all phases of diseases of the chest and the fundamentals of x-rays. The great importance of the inclusion of x-ray inspection as a part of every examination of the chest has been emphasized in several quarters since the first world war. However, students of chest diseases have not recommended that any examination of the chest be limited to x-ray inspection or that any examination for tuberculosis be limited to the chest. Therefore Hilleboe and Morgan have not confined their book to x-ray inspection, as one might infer from its title.

Although the bulk of the book is devoted to such subjects as history of mass radiography, equipment available for mass radiography, phototimers and automatic cameras, physical factors affecting the choice of equipment, designs for mass radiographic installations, roentgen technic in mass radiography and the future development of mass radiography, there are excellent chapters on such subjects as objectives of tuberculosis control and the study and care of persons with abnormal films.

In a chapter on diagnosis the authors state that x-ray inspections constitute diagnostic screening procedures by which the abnormal are separated from the normal. Obviously this applies only when macroscopic (pathologically gross) lesions are present and are of sufficient density to absorb x-rays. Lesions of smaller size and less density cast no visible shadows. The authors point out that in many cases it is quite impossible to identify the various diseases of the chest which cast shadows. They rightly state that this should not be cause for concern, for "if an x-ray examination does nothing more than indicate the presence of a pathological process it has made a worth while contribution, especially if the process is unsuspected." If every physician would recognize this fact and so use the x-rays, this phase of the examination would serve a much more useful purpose than has been true in many instances in the past. The authors call attention to the fact that, once the presence of disease is detected by the shadow it casts, its etiology usually can be determined by other methods.

A fine array, in fact more than forty x-ray reproductions, is presented. In some of them diagnostic impressions are given without much other evidence than the shadows, but in the majority the actual diagnosis is given when other more exact evidence was available, such as recovery of specific organisms, a study of biopsy material, history of exposure to hazardous dust, presence of tuberculin reaction and postmortem examination. These reproductions of shadows, together with other diagnostic evidence presented, is an excellent demonstration of the proper use of the x-rays.

When a lesion has been definitely identified as tuberculous, all too often one sees reports made from one film of the chest, including such words as active, quiescent, arrested, healed, stable, unstable, first infection type and reinfection type. With reference to determination of activity of a given lesion from the shadow it casts, the authors rightly state, "Notwithstanding

the fact that there was a time when we sincerely believed that this question could be answered from the appearance of a single film alone, recent experience indicates that it is extremely difficult in most instances to do so. Before a process can be considered definitely active, progressive changes in subsequent roentgenograms or positive laboratory and clinical findings, such as a tuberculin reaction, tubercle bacilli in the sputum, or gastric washings, and increased sedimentation rate and fever, should be demonstrated." The correctness of this statement is obvious to all students of tuberculosis.

As long as the limitations of mass radiography employing photofluorograms as well as regular size x-ray films is explained and understood by all concerned, it is highly desirable to use the x-rays in screening the chests of any group of individuals, no matter how small or how large. Indeed, it should be extended to every citizen, as it detects the presence of gross lesions in the lungs, mediastinum and pleura, regardless of etiology, as well as changes in the cardiac outline, among persons in whom they are not suspected.

Four principal phases of an effective tuberculosis control program are discussed: (1) case finding, (2) medical care and isolation, (3) after-care and rehabilitation, (4) protection of the tuberculous family against economic distress. These four fundamental procedures are presented in such a manner as to convince the reader that Hilleboe and Morgan have a clear vision of satisfactory tuberculosis control throughout the country. This undertaking deserves the support of the entire medical profession and all of its allies in developing and carrying out a nationwide tuberculosis control program which ultimately could prove to be as successful as that which the veterinarians instituted and conducted against tuberculosis among cattle.

Tropical Medicine. By Sir Leonard Rogers, K.C.S.I., C.I.E., M.D., and Sir John W. D. Megaw, K.C.I.E., B.A., M.B. Fifth edition. Cloth. Price, \$6.50. Pp. 518, with 89 illustrations. Baltimore: William Wood & Company, 1944.

The authors of this compact manual of tropical medicine are unusually well qualified not only by many years' duty with the Indian Medical Service but also by virtue of considerable experience as teachers and advisers in their specialty. Each contributed basic original studies and each rose to positions of major administrative responsibilities in India. It is not surprising that five editions of their book have appeared since it was published in England in 1930.

This work was planned to emphasize the recognition and management of the diseases commonly encountered in tropical and subtropical countries, with a minimum of discussion of laboratory and parasitic phases. The book gives a broad survey and is an introductory treatment of the subject.

The twelve sections cover respectively the fevers caused by protozoa, spirochetes, filtrable viruses, rickettsia bodies and bacteria; bowel diseases; diseases with prominent skin lesions; helminth diseases; diseases caused by venomous animals, diet, heat and light, and finally a miscellaneous section which includes a discussion of disease incidence in the tropics, hints on use of the microscope and some general remarks on the diagnosis of fevers. This fifth edition presents considerable revision in the chapters on malaria, kala-azar, trypanosomiasis, rickettsial diseases and those associated with diet.

As in previous editions, preventive aspects of the subject receive considerably less attention than clinical. Inevitably there must be a considerable interval between manuscript and published book, and this doubtless explains such important omissions as a discussion of the large initial dose of atabrine in the first twenty-four hours, now generally considered standard when this drug is used in treating malaria.

The format is not up to usual standards, but the type is clear and the figures are useful. The illustrations are few and generally poor. The two colored plates are crowded and leave much to be desired. There is no bibliography.

This book does not take the place of such a classic as the Stitt-Strong treatise on Tropical Medicine, and it does not have the balance of the recent *Manual of Tropical Medicine* by Mackie, Hunter and Worth. But it contains a very useful presentation of the clinical aspects of the important tropical diseases, soundly based on the unusually extensive practical experience of the authors.

Your Hair and Its Care. By Oscar L. Levin, M.D., and Howard T. Behrman, M.D. Cloth. Price, \$2. Pp. 184, with 10 illustrations. New York: Emerson Books, Inc., 1945.

This "attempts to present in simple fashion the most recent scientific knowledge concerning hair, hair disease and the proper care of the normal scalp." Unfortunately, the authors have not fulfilled their assignment creditably. The first sentence in the book calls for challenge: "Few branches of medicine have made such progress in the past ten years as has the one concerning diseases of the hair and scalp." There are misleading inaccuracies throughout the book, as "Constipation is the root of a vast amount of baldness; a great deal can be done to prevent premature grayness; hair pins and hat pins are injurious to good hair growth; those who know that early baldness is a family trait should make particular efforts to prevent its coming; senile baldness should be guarded against before it appears." Writing expressly for the public, the authors have written simply, but with an inclination occasionally to facetiousness. The newer knowledge with regard to vitamins and endocrines is discussed briefly and adequately, yet on another page there is given the detailed technic for colonic irrigation. The last chapter, which consists of questions and answers, is particularly good, but the book as a whole hardly merits recommendation.

La dirección general de higiene de la Provincia de Buenos Aires. Por el Dr. Juan Leon, profesor adjunto de clínica obstétrica y docente libre de clínica ginecológica de la Facultad de ciencias médicas de Buenos Aires. Algo de la labor desarrollada especialmente en el terreno de la protección maternal e infantil. Paper. Pp. 203. Buenos Aires: "El Ateneo," 1944.

This book, published at his expense by the author, who is also assistant professor of obstetrics in the Buenos Aires Medical School, describes his experiences during the brief period (January-July 1944) when he acted as director of public health of Buenos Aires, the largest province of Argentina. A full account is given of the organization of the provincial health department and then more in detail the mother and child welfare activities carried out by the department since a special division was created at the author's suggestion for that purpose in the early part of 1944. The department controls fifteen hospitals in the province, a maternity with a school for midwives, five mother and child welfare stations, a nursery and other institutions. A number of other works were either under way or planned when the author left office. The budget of the department for the year 1944 was over 8,300,000 pesos, which represented a considerable increase over 1943.

Inebriety, Social Integration, and Marriage. By Selden D. Bacon, Ph.D. Memoirs of the Section on Alcohol Studies, Yale University, No. 2. Paper. Price, 75 cents. Pp. 76. New Haven, Connecticut: Quarterly Journal of Studies on Alcohol, 1945.

This reprint booklet attempts "to illustrate the possibilities of a sociological approach to a limited portion" of the problem of inebriety. It is a statistical paper supporting the personal conclusions of some workers in the field of alcoholism. While of some academic interest, it has no practical value for the practitioner.

What to Do About Vitamins. By Roger J. Williams. Cloth. Price, \$1. Pp. 56, with 31 illustrations. Norman, Oklahoma: University of Oklahoma Press, 1945.

A competent nutritional scientist has presented in this little book the important facts of nutrition in a simple manner. The material covers more than the title suggests. The effects of food intake on body weight, emotional attitudes and the results of improper eating are discussed. The primary objective, however, is to provide assistance in straightening out the existing confusion with regard to vitamins. The functions of vitamins are compared to the lubricants for machines. They are obtained from foods eaten, and most dependably from a variety of foods. The dangers of using too much of certain foods such as white rice, refined sugar and flour are appropriately pointed out. Advice is given for guarding against loss of vitamins in the cooking of foods that contain vitamins. Throughout the book the author's experience with the nutrition of growing animals is utilized to emphasize the effects of good and poor nutrition. Readers may anticipate advice on the selection and use of vitamin preparations, but this is not the case. Emphasis is placed

on foods as the proper source of nutrition, although the value of vitamin capsules under special conditions is not denied. To assist the reader in applying the principles discussed, diagrams are given providing visual comparison of the quality of foods. The simplicity of explanation and the multiplicity of examples make the book particularly valuable in orienting those confused or uninitiated in nutritional matters.

Tales from the Inns of Healing of Christian Medical Service in India, Burma and Ceylon. Prepared Under the Direction of the Executive Committee of the Christian Medical Association of India, Burma and Ceylon, P. V. Benjamin, President. Foreword by Rev. J. Z. Hodge, D.D. Canadian edition Paper. Price, \$1.25. Pp. 162, with illustrations. Toronto: The Committee on Missionary Education, The United Church of Canada; New York: Friendship Press, 1944.

A collection of unusual accounts from the mission hospitals in India, Burma and Ceylon that are operated by Christian Medical Service comprises the major portion of this small book. The struggles and difficulties of the pioneers in medical and hospital care are vividly retold in many anecdotes throughout the book. Modern scientific medicine, surgery and obstetrics was made available to a limited number of the lower classes in India through the mission hospital staffs. Much has been accomplished in establishing and furthering good schools of medicine and nursing for native Indians as a means of helping them solve some of their tremendous medical care problems. It is an interesting collection of reports of the valiant efforts of a few in their attempt to relieve the disease and distress of the forgotten man of India.

Contribución al estudio de los reduvidos hematofagos de Guatemala. Por Ernesto Blanco Salgado. Tesis presentada a la Facultad de ciencias médicas de la Universidad nacional, Guatemala, en el acto de su investidura de medico y cirujano. Publicaciones de la Dirección general de sanidad pública. Paper. Pp. 54, with 18 illustrations. Guatemala, C. A., 1943.

This booklet contains valuable information on the vectors of Chagas disease present in Guatemala and their morphology, distribution and habitats. It is to be noted that in spite of the varied and rich fauna of the country only two genera of Reduviidae are to be found, and each is represented by a single species, *Triatoma dimidiata* and *Rhodnius prolixus*, both proved carriers of American trypanosomiasis and both found naturally infected in Guatemala.

The Hair and Scalp: A Clinical Study (with a Chapter on Hirsuties). By Agnes Savill, M.A., M.D., F.R.C.P.I. Third edition. Cloth. Price, \$4.75. Pp. 304, with 54 illustrations. Baltimore: William Wood & Company, 1945.

This is an excellent book and is as up to date as a current medical journal. The subject is covered completely, from structure and physiology of the hair to discussions of endocrinology, hair dyes, permanent waves and hirsuties. Although Savill is strongly influenced by the teaching of Sabouraud, she gives the views of opposing schools, and the result is a clearly expressed personal book which includes frequent references to pertinent case reports. This volume contains twenty short chapters dealing with normal and diseased scalp and hairs, simply classified under such captions as "itching of the scalp," "gray hair," "diffuse hair fall," "hairfall with bald patches" and "scaly conditions of the scalp." Altogether it is an authoritative book, written with charming simplicity by a woman who has obviously studied the subject matter intensely and with sympathetic understanding, for "to women their [maladies of scalp and hair] may indeed color all life with tragedy." The book is highly recommended.

Índice bibliográfico de lepra 1500—1943. Volume I: A-H. Organizado por Luiza Keffer, biblioteca do Departamento de profilaxia da lepra de São Paulo. Paper. Pp. 674. São Paulo, 1944.

This index catalogue of works on leprosy is obviously the largest and most exhaustive reference list on any special medical subject so far published anywhere. Its publication constitutes a real service rendered by the Department for the Prevention of Leprosy of the State of São Paulo, Brazil, and especially its library, to a better knowledge of one of the diseases of most importance in some areas of the Americas. The mere list of journals embraces sixteen pages. The first volume covers only letters A to H. Leprologists and sanitarians, as well as bibliographers, will await with interest the appearance of the volumes reviewing the remaining letters of the alphabet.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BCG VACCINE FOR TUBERCULOSIS

To the Editor:—There have been numerous reports on the protective value of BCG vaccination against tuberculosis. Has this been used in this country? If so, where may one get the material and what is the technic?

A. I. Love, M.D., Chicago.

ANSWER.—There have been numerous reports on the protective value of BCG vaccination against tuberculosis. In fact, since 1922 more than two million children, as well as some adults, have been vaccinated. Most of this work has been done in Europe, Africa and Asia; it has been employed to a much smaller degree in the Western Hemisphere. Although considerable optimism has been expressed, there are many who definitely oppose the procedure because the vast majority of studies have not been well controlled. Levine has called attention to the fact that ideal control calls for consideration of the following variables:

1. Environmental conditions: (a) intelligence and cooperation of parents; (b) differences in locality; (c) differences in time during which controls of vaccinated patients are studied.

2. Exposure conditions: (a) frequency of exposure; (b) amount of sputum expectorated; (c) number of micro-organisms in the sputum; (d) intensity of exposure.

3. Other factors: (a) age at first exposure; (b) racial differences; (c) reliable diagnosis at death; (d) identical follow-up of control and vaccinated patients; (e) maintaining contacts with all cases; (f) freedom from exposure for similar periods in both groups if separation is advisable for either group; (g) study of adequate numbers of subjects to minimize results of chance distribution.

Levine points out that in no study thus far reported have all these factors been considered and adequately controlled. Therefore, until such a controlled study has been made and reported, the efficacy of BCG vaccination will not be definitely known. Milton I. Levine of the Department of Pediatrics, Cornell University Medical College, New York City, has recently prepared an excellent analysis of a study on the efficacy of the BCG vaccine conducted by the Bureau of Laboratories of the New York City Department of Health between December 1926 and January 1944.

Alberto Chattas of Cordoba, Argentina, has published an elaborate monograph on this subject. In Canada, J. A. Baudouin of Montreal and R. G. Ferguson of Saskatoon have conducted extensive experiments. J. D. Aronson of the Henry Phipps Institute, University of Pennsylvania, Philadelphia, and J. D. Townsend of the Office of Indian Affairs, Department of the Interior, Washington, D. C., have in progress a rather extensive study on the efficacy of BCG in controlling tuberculosis among American Indians. S. R. Rosenthal of Chicago has evinced considerable enthusiasm for the administration of BCG. An extensive and prolonged study of BCG in controlling tuberculosis among cattle of the United States has been reported. The results of this work may be obtained from A. E. Wight, Chief of the Division of Tuberculosis, United States Bureau of Animal Industry, Washington, D. C. The technic of administration and the source of material can be obtained from any of the physicians mentioned.

WELDING AND THE PARATHYROIDS

To the Editor:—A man aged 43 has chronic tetany. He has been doing electric arc welding. Could the rays have any effect on the parathyroids?

William A. Doebele, M.D., Huntingdon, Pa.

ANSWER.—One by one the various internal secretory organs are suspected of being a site of harmful action of arc welding products: first the testes, with emphasis on impotence, and then the ovaries, with emphasis on sterility. For none of these is there proof that the rays derived from arc welding have any harmful properties. Moreover, in tetany from involvement of the parathyroids ultraviolet rays, which are the rays produced in arc welding, have some value in therapy. Aub states that "by ultraviolet light calcium absorption from the intestines is improved, and calcium is also liberated from the bones. This effect is obtained only after several days. This treatment is of effect in all tetanics with low blood calcium." With emphasis value in all tetanics with low blood calcium." With emphasis on the probability of coincidence in the occurrence of tetany in

arc welding, two speculative possibilities may be mentioned. 1. In many types of electrical application, but not necessarily arc welding, large electrical fields are set up. It is possible, but little proved, that highly numerous minor electric fields may be set up within the body on an organ basis. Granting such a possibility, there still is lacking any knowledge of its physiologic import. 2. Arc welding may involve the use of many metals and chemicals, particularly if the welding is carried out with coated electrodes. Manganese, chromium, lead, fluorine and many others are in use; certain of these substances, such as lead and fluorine, upset the normal metabolism of calcium and phosphorus. Tetany is a condition characterized by the same sort of disturbed metabolism. In the *Lancet* (1:148 [Jan. 30] 1943) appears a note entitled "Fluorine and the Parathyroids." However, direct observation on small laboratory animals fed fluorine in toxic doses revealed no damage to the parathyroids, although some other organs were severely injured. In an article by K. Reinhart entitled "The Relation of Lead Poisoning and Parathyroid" (*Arch. f. Gewerbepath. u. Gewerbehyg.* 9:80, 1938) the findings imply that in chronic lead poisoning a condition may arise bearing some similarity to tetany.

General discussion of tetany and parathyroid diseases may be found in such publications as:

Meakins, Jonathan Campbell: *The Practice of Medicine*, St. Louis, C. V. Mosby Company, 1936.
Cecil, Russell L.: *A Textbook of Medicine*, Philadelphia and London, W. B. Saunders Company, 1937.

THE VAGINAL DOUCHE

To the Editor:—I am interested in the origin of the word douche and the earliest references from a purely hygienic point of view. There are many references regarding early intrauterine and vaginal douching during labor and the postpartum period, also as a therapeutic measure, but I am interested particularly in the mechanical aspect, as employed by the French, for instance, as a daily routine. Is it possible to furnish me with historical references concerning the douche from the standpoint I have outlined?

M.D., District of Columbia.

ANSWER.—The word douche is French and signifies a shower bath. However, in the English language the word is used to describe a stream of water directed against a part or into a cavity (*American Illustrated Medical Dictionary*). As generally used nowadays by both physicians and the public the word douche nearly always refers to a spray of water directed into the vagina either for purposes of cleansing or for therapeutic reasons.

Douches have been used for many centuries. Hippocrates, who died in 357 B. C., mentioned that vaginal irrigations were used extensively for vaginal and uterine diseases. Douches are used all over the world. The French have developed a special kind of douche which is used most extensively in France and is known as a bidet. This particular type of douche is used chiefly from a hygienic point of view and the apparatus for its use is really a sitz bath. Incidentally, the word bidet in French also means "pony" or "nag" and the woman usually sits on a bidet as one rides a horse. French women use the bidet both for external cleansing of the vulva and for vaginal douching. For many years the bidet has been the only plumbing equipment for bathing to be found in many bedrooms in France.

THROMBOANGIITIS OBLITERANS

To the Editor:—Is there any indication that heredity plays a part in the etiology of Buerger's disease? What is the usual cause?

Perry B. Preston, M.D., Newark, N. J.

ANSWER.—Buerger's disease may occur in members of the same family; brothers are sometimes affected. However, there have not been enough cases studied over two or more generations in family groups to permit any definite conclusions. The cause of the disease is unknown.

DOSAGE OF TESTOSTERONE

To the Editor:—With reference to the answer to the query on Dosage of Testosterone Propionate in *The Journal*, July 14, 1945, page 838, may I put in a word of dissent? In the past year I have given testosterone propionate in 25 mg. doses three times weekly for three weeks to 2 men aged over 65 years. The first patient died six weeks later of an enormous carcinoma of the stomach. X-rays of the stomach taken prior to institution of the androgen therapy were negative and still look so in retrospect. The second man died about a month after termination of therapy of a rapidly growing retroperitoneal sarcoma. Probably both neoplasms were present prior to institution of the therapy, but the rapidity of their growth and their apparent stimulation by the androgen simply appalled me, so much so that I have now made it a rule to give no such treatment to any man over 60.

AN INTERPRETATION AND EVALUATION OF TUBAL PATENCY TESTS

NORMAN F. MILLER, M.D.
ANN ARBOR, MICH.

There are today two widely accepted methods of determining tubal patency, uterotubal insufflation and uterosalpingography. Rubin¹ first performed uterotubal insufflation in 1919, using oxygen gas. Salpingography began a few years earlier, when Cary² and Rubin³ in this country carried on independent studies in an attempt to visualize the tubes radiographically. Rindfleisch⁴ had previously attempted visualization of the uterine cavity in 1910. Since their inception almost a quarter century ago both tests have been discussed in the literature and there is no need to repeat their historical development here. Their widespread use and almost universal acceptance offer ample testimony to the fact that both have emerged from the chrysalis stage. Both have come to occupy an important place in the study of female sterility. Since equipment and steps in technic have also been thoroughly described, there is likewise little reason for their recapitulation here. On the other hand, a crystallization of important points gleaned from an extensive literature and a personal experience dating back to 1921, covering hundreds of tubal insufflations and over 400 cases of uterosalpingography may be appropriate in this symposium. Both uterosalpingography and uterotubal insufflation are commonly used for determination of tubal patency and for the two the contraindications are the same. While these have been listed many times they are so important that I shall repeat them here.

CONTRAINDICATIONS TO PERFORMING TUBAL PATENCY TESTS

The most important contraindication to the performance of a tubal patency test is the presence of genital tract infection. Most morbidity following tube testing results from failure to recognize or discover cervicitis or incompletely subsided salpingitis. Since careful and satisfactory evaluation of genital infection is not always possible at the time of the initial call, it is seldom wise to determine tubal patency at the time of the first visit. By deferring the test the physician not only obtains more time for the study of his patient but may also schedule the test at a selected time during the menstrual cycle.

From the Department of Obstetrics and Gynecology, University of Michigan Hospital.

Read before the Conference on Sterility, sponsored by the National Committee on Maternal Health Inc., New York, Jan. 27, 1945.

1. Rubin, I. C.: The Nonoperative Determination of Patency of Fallopian Tubes by Means of Intrauterine Inflation with Oxygen and the Production of an Artificial Pneumoperitoneum, *J. A. M. A.* 75: 661 (Sept. 4) 1920.

2. Cary, W. H.: *Am. J. Obst.* 69: 462, 1914.

3. Rubin, I. C.: *Surg., Gynec. & Obst.* 20: 435, 1915.

4. Rindfleisch, W.: *Berl. klin. Wchnschr.* 47: 780, 1910.

Pregnancy is an obvious contraindication. Knowledge of the patient's menstrual history and repeat pelvic examination just prior to tube testing is important.

When uterotubal insufflation is contemplated, air should not be used. While it has been employed extensively it must not be forgotten that most deaths reported following uterotubal insufflation were the result of air embolism.

Determination of tubal patency may be carried out at any time during the cycle, but most investigators prefer the week after menstruation. Time and experience have shown that if living endometrial cells are forced through the tubes they seldom survive, and furthermore perturbation appears to be more satisfactory when the endometrium is in a stage of minimal development and the tube quiescent. General constitutional disease and/or pelvic neoplasia associated with abnormal bleeding are other contraindications.

My interest in tubal insufflation began following Rubin's¹ original report on "The Nonoperative Determination of Patency of Fallopian Tubes" in 1920, at which time it was my privilege to be associated with Dr. Reuben Peterson, whose enthusiasm for pneumoperitoneum was well known. Significant improvements in apparatus such as the recording kymograph, introduced by Rubin in 1925 and modified by him in 1939, plus a variety of cannulas, represent the principal mechanical changes in the growth and development of uterotubal insufflation. As an aid in running down the causes of sterility in women the test remains indispensable. In the average nonfertile union, when the husband has been eliminated as a likely cause, an adequate history taken and such other preliminary studies as physical examination made, then uterotubal insufflation, under proper indications, becomes a logical and necessary procedure. According to reports approximately 60 per cent of women so studied present unequivocal evidence of tubal patency. About 30 per cent are found to have closed tubes.

Since the determination of tubal patency or nonpatency is the primary air of insufflation, the addition of a kymograph which permits recording of both gas pressure and tubal behavior may seem an unnecessary appurtenance. From a practical standpoint this addition has been more than compensated for by the minimum equipment and simplified apparatus also available for tube testing. Certainly, uterotubal insufflation may be accomplished without elaborate equipment. But, regardless of technic used, determination of tubal patency depends on evaluation of the following points:

1. Behavior of manometric pressure.
2. Careful evaluation of subjective symptoms such as pain in the lower quadrants (tube areas).
3. Auscultation (of the tubes) over the lower abdomen.
4. Checking for the presence of shoulder pain (subdiaphragmatic pneumoperitoneum) following the introduction of approximately 300 cc. of gas (patient sitting up).

5. Noting the kymographic recording of intratubal pressure and activity.

6. When uterosalpingography is used, the fluoroscopic observation of spill from the tubal ostia or roentgenographic visualization of free oil in the peritoneal cavity following injection of an opaque medium.

Pressure observations are important. Perhaps it does not matter whether this is read directly on a manometer or indirectly as when a recording kymograph is used, so long as pressure determinations are noted. Failure to observe pressure may lead to serious trouble. With a constant and not too rapid flow of gas (approximately 60 cc. per minute) the pressure normally rises to about 120 mm. of mercury and then drops to between 40 and 60 mm., where it tends to remain for the remainder of the test. Progressive and persistent rise in pressure may mean nonpatency. This may be apparent or real. It may be due to spasm of the sphincters sometimes noted in highly irritable tubes, especially at the time of ovulation, to a valvelike effect caused by a thick, velvety, premenstrual endometrium or to an actual organic obstruction. Many physicians failing to use care in the interpretation of pressure changes have diagnosed tubal closure and given a poor prognosis for conception, only to swallow their words when the happy and forgiving patient reports for antepartum care. Gas pressure writes its own story when recorded on a kymograph, and its interpretation along with minor fluctuation due to tubal peristalsis permits informative interpretation regarding tubal physiology.

Uterotubal insufflation without a constant source and flow of gas or benefit of manometric check on pressure as described in simplified technics is not recommended. Since air is commonly used in these abbreviated methods, there is danger of embolism as well as increased opportunity for faulty interpretation of findings.

The patient's subjective complaints during tube testing are likely to be informative, thus:

1. Bilateral lower quadrant pain with steady progressive rise in pressure usually means bilateral closure of the tubes at the fimbriae.

2. Bilateral pain with high but steady pressure (below 180 mm. of mercury) usually means bilateral narrowing of the tubal lumens at the fimbriae.

3. Unilateral pain with slightly elevated pressure means unilateral closure at the fimbria on the painful side.

4. Midline pain with steadily rising pressure means bilateral closure (or spasm) at the corneal ends of the tubes.

The interpretation of subjective symptoms should not be clouded by irregular or too rapid introduction of gas.

Auscultation of the tubes over the lower part of the abdomen was first suggested by Henderson and Amos.⁵ The gas percolating from the ends of the tubes may be heard as a low pitched soufflé. A high pitched note generally implies a small opening or excessive pressure. One cannot always identify the open tube by this means, since the tubal fimbriae may lie close together behind the uterus. Deception may occur as a result of gas bubbling through a hydrosalpinx or more frequently from a leak around the cannula in the cervix. The Colvin screw-type cannula minimizes leakage and does away with the need for tenacula on the cervix but has the disadvantage of not permitting escape of gas under excessive pressure.

Shoulder pain coming on when the patient sits up immediately after insufflation is one of the standard

confirmatory tests for tubal patency. It is due to subdiaphragmatic pneumoperitoneum and may affect either shoulder. The introduction of approximately 300 cc. of gas is necessary to produce this discomfort.

Kymographic recordings of gas pressure and tubal behavior are helpful and probably should be part of modern tubal insufflation equipment. The records so obtained may be interpreted quickly and form a permanent part of the patient's study. For details of tube graph evaluation reference should be made to basic contributions on this subject by Rubin,⁶ Wimpfheimer⁷ and Feresten⁸ and others.

INTERPRETATION OF TUBAL INSUFFLATION

I have already mentioned the criteria by which a diagnosis of tubal patency may be made following insufflation. When these criteria are present it is safe to assume that at least one tube is open. In the absence of such criteria it is to be presumed that the tubes are closed. While this presumption will generally prove correct, it is well to remember that closure may not be permanent and consequently a discouraging prognosis should not be given until closure has been confirmed by repeated testing on several different occasions.

In general, tubal insufflation is the procedure of choice for initial investigation of patency. When stenosis or complete closure has been diagnosed, a further check by means of uterosalpingography may be desirable, since it permits more accurate localization of the obstruction and allows better selection of cases for salpingostomy.

UTEROSALPINGOGRAPHY

At the University of Michigan Hospital during the past decade we have performed uterosalpingography over four hundred times. Approximately 300 were sterility patients; the remainder were checks on tube continuity following ligation or resection.

While the technic for tube visualization is well known, it may be well to emphasize those points which have an important bearing on maintaining this test as a highly successful and safe procedure.

The contraindications are identical with those already listed for uterotubal insufflation, genital tract infection being the most important stop sign.

As with gas insufflation, excessive pressure must be avoided. For highly informative thoroughly safe results all oil injections should be carried out under fluoroscopic control, taking care to use warm opaque mediums and only enough (6 to 10 cc.) to maintain adequate filling of the uterine cavity. The opaque medium used is a matter of considerable importance and should meet the following requirements:

1. It should give good contrast on roentgen visualization.
2. It must have sufficient consistency to permit ample time for study, including follow-up roentgenograms.
3. It should be neither too rapidly nor too slowly absorbed.
4. It must not cause irritation of mucous membranes or peritoneum.
5. It must be safe to use.

While none of the opaque mediums available appear to fulfil all these requirements satisfactorily there is every reason to believe that one will be found. Indeed, when an ideal medium becomes available we may also find that it contains many remedial and therapeutic

properties now merely foreshadowed by existing preparations. In our hands lipiodol has proved quite satisfactory, although its slow absorption and possible irritant qualities are undesirable features. Rubin⁹ prefers visco-rayopake, while Titus, Tafel, McClellan and Messer¹⁰ recommend skioldan-acacia.

All patients in our study represent a cooperative effort in that the fluoroscopic examination is under the direct control and visualization of both roentgenologist and gynecologist. Much valuable data are obtained in this way. The filling of the uterine cavity and the slow passage of oil out into the tubal lumens may be observed directly. Leakage from the tubal ostia into the peritoneal cavity or around the cannula in the cervix may be noted and controlled. Since direct injection in the darkened fluoroscopic room does not permit ready pressure observation, the tension may be regulated by visualizing the filling of the uterine cavity and by noting the patient's subjective symptoms. A manometer with luminous gradations would permit accurate pressure recordings and a higher margin of safety. Evidence of tubal patency may be obtained at this time by seeing droplets of oil disappear from the outer ostia of the tube. This should be confirmed by roentgenograms taken following the fluoroscopic study. Since roentgenograms serve as a permanent record of findings, they should be obtained in every instance. In cases of doubtful patency or nonpatency, a twenty-four or forty-eight hour checkup roentgenogram is essential. These follow-up plates are highly important. They either confirm the nonpatency or else reveal definite but late escape of oil through the tubal ostia. Failure to take advantage of fluoroscopic examination and control at the time of injection and of roentgenographic follow-up studies some hours after injection doubtless accounts for some of the complications as well as faulty interpretations attributed to uterosalpingography. The presence of oil in the peritoneal cavity is proof of tubal patency.

INTERPRETATION OF UTEROSALPINGOGRAPHY

When tube status remains in doubt following insufflation or when salpingostomy is contemplated for tubal obstruction, salpingography comes into its own. For these cases it reigns supreme as a diagnostic test. In my opinion the localization of tubal obstruction permitted by uterosalpingography is far superior to any evidence made available through insufflation alone. This means that in approximately one third of women studied for sterility uterosalpingography serves as a useful and important diagnostic and prognostic aid. While fluoroscopic and roentgenographic findings during and after iodized oil injection are not difficult to read, their interpretation demands care. Final decision regarding nonpatency should not be based on fluoroscopic findings alone. A twenty-four or forty-eight hour checkup roentgenogram may show definite spill of oil into the peritoneal cavity—evidence that obstruction has at least in part been overcome. Spasm, when present, may vary in degree on the two sides; consequently the true status of both tubes may not always be clear at the time of injection. However, temporary occlusion is less likely to be misinterpreted with salpingography than with insufflation, since the follow-up roentgenogram showing oil in the peritoneal cavity tends to disprove the first gained impression of nonpatency.

MORBIDITY AND MORTALITY

Important in the evaluation of any test is the risk to the patient. We have no way of knowing how many deaths and to what extent febrile morbidity has occurred following the use of these tests. Certainly it is improbable that reported cases represent the whole story. On the basis of data available, it appears that less than 1 patient in a thousand suffers any morbidity following uterotubal insufflation. Morbidity following uterosalpingography is higher. Most trouble appears to have resulted from failure to rule out genital tract infection.

Injection of oil into the uterine and ovarian veins during salpingography has been reported many times. The symptoms associated with this complication do not appear to be severe and according to Green-Armytage¹¹ consist of little more than transient nausea and vomiting. Actual visualization of oil in the pelvic veins following salpingography should not blind us to the fact that this accident probably occurs quite as often during uterotubal insufflation. Since air embolism may be a serious matter, it is well to emphasize again the desirability of using the more soluble carbon dioxide for tubal insufflation.

The mortality rate must be extremely low and in gas perturbation was caused chiefly by air embolism. At least 6 cases have been reported, to wit:

1. Moench.¹² Gas inflation, tubes closed, death. Autopsy revealed gas in the heart chambers. Gas embolism diagnosed as cause of death.
2. Moench.¹² Oxygen insufflation, tubes patent at 200 mm. of mercury, death. Autopsy revealed gas in the heart, veins and abdomen, perforated small intestine and a question of perforation of the uterus.
3. Dibble, Hewer, Roes and Walsh.¹³ Tubal insufflation pressure at 150 to 200, sudden death. Autopsy revealed air embolism.
4. Mansfield and Dubits.¹⁴ Gas insufflation, death. Autopsy revealed tuberculous endometritis and air embolism.
5. Weitzman.¹⁵ Insufflation, convulsion and death. Autopsy revealed air embolism.
6. Feiner.¹⁶ Woman aged 26; insufflation with oxygen pressure at 160 mm. of mercury. Death within one-half hour. Diagnosis, rupture of coronary vein, hemipericardium, pulmonary thrombosis and chronic myocarditis.

I have been unable to discover any recorded fatality following the use of carbon dioxide. At least nine deaths have been reported following uterosalpingography. Most of these deaths are reported in European literature and I have not been able to run down the original articles to permit a check on the actual cause of the fatality. Deaths following uterosalpingography follow. This may not represent a complete list and obviously does not include unrecorded cases:

1. Gauss.¹⁷ Five deaths in 3,000 collected cases.
2. Schultze.¹⁸ Three deaths in 8,000 collected cases.
3. Feiner.¹⁶ One death. Patient died fourteen days following lipiodol injection, of widespread generalized peritonitis.

Most fatalities following the use of either air or oil occurred in the earlier years when the patency tests were in their developmental stage.

EVALUATION OF TUBAL PATENCY TESTS

In the past, uterotubal insufflation and uterosalpingography have been looked on as competitive tests, and this they doubtless are, for both are methods of determining tubal patency. Now that both have been thoroughly tested and proved, it is proper that they be looked on as complementary procedures, one supplementing the other. As the initial step in determining tubal patency, insufflation is to be preferred. In the majority of cases this test alone will give all needed information. For doubtful cases and in cases presenting definite evidence of nonpatency I prefer uterosalpingography with its visual proof of tube status and opportunity for better evaluation when salpingostomy is considered. Iodized oil injection may exert a therapeutic effect on the closed viscus. Repeated iodized oil injection may be expected to result in reopening a few closed tubes. Just how often this will occur must depend in large measure on the severity of the obstruction as well as on the number of reinjections carried out. No accurate statistics can be given on this point. A comparison of the tests from the standpoint of diagnostic value would doubtless precipitate many arguments both for and against each method. Such comparisons as have been carried out in the past have served to emphasize the importance of interpretation. The fact that one test shows nonpatency whereas patency is proved by the other test a few days later does not indicate superiority of one method over the other as a means of determining tubal continuity. The situation could easily have been reversed and is readily explained on the basis of tube spasm or other transitory interference with patency. Both tests are useful, and while either will permit evaluation of tubal patency they each have a particular field of usefulness in the study of sterility and of tubal physiology. For the determination of patency alone insufflation with carbon dioxide is given first choice, but this test is useless as a means of visualizing the tubes and it is here that the salpingogram dominates the field. It is in this manner that the tests supplement each other.

I consider uterosalpingography an essential preliminary to contemplated salpingostomy. Furthermore, such operative procedure on the tubes should not be carried out until several checks for tubal patency have been made, since it is well known that spontaneous restoration of tubal continuity occasionally takes place.

There can be no doubting the fact that both tests have a therapeutic as well as a diagnostic value. The fact that pregnancy occurs within a month or two after tubal patency determination is proof of such therapeutic value. Doubtless success is accomplished by mechanical means through the removal of a mucous plug or old blood or the disruption of adhesions which may have been sufficient to interfere with migration of the ovum.

Many writers have attempted statistical evaluation of tubal patency tests. Such mathematical assay is interesting and could be valuable were there some way of obtaining reasonable accuracy. However, the fact that many patients conceive without benefit of medical aid, while others receive local and/or general treatment in addition to tube testing, makes statistical evaluation something little better than a guess. This is especially true when many months have elapsed between the test and the time of conception. Since reported series probably represent a small minority of the total tube testings carried out throughout the world, and these under

favorable conditions at that, it is obvious that data on therapeutic benefits as well as on morbidity are grossly inaccurate and incomplete. The most that can be said is that when properly performed the morbidity following tube testing is extremely low. We should not assume too much in the way of remedial benefit from the use of these tests. The occasional resolution of tubal obstruction as a result of repeated iodized oil instillations has been claimed. I have noted a return of patency in some patients following repeated injections. This apparent remedial aspect of uterosalpingography is difficult to evaluate but in time and with improved injection mediums may prove to be a real boon to sterility patients.

Uterotubal insufflation with carbon dioxide gas and uterosalpingography are today the principal two methods of studying tubal patency and physiology in the human being. These tests should not be looked on as competitive procedures, for each has its field of usefulness as well as its limitations. One supplements the other, and both are essential for comprehensive evaluation of the part played by the tubes in sterility of the female. When properly performed with full knowledge of both indications and contraindications, they are safe and highly informative.

THE INCIDENCE OF DIABETES MELLITUS AND GLYCOSURIA IN INDUCTEES

WITH NOTES ON SOME PROBLEMS IN DIAGNOSIS

MAJOR M. A. SPELLBERG

AND

LIEUTENANT COLONEL WILLIAM A. LEFF

MEDICAL CORPS, ARMY OF THE UNITED STATES

The statistical observations in this paper were stimulated by the editorial¹ appearing in THE JOURNAL on April 8, 1944. The high incidence of diabetes mellitus found by Blotner and his co-workers² in urban New England warranted a study in another part of the country where other economic, social and racial factors are at work.

This survey is based on 32,033 consecutive selectees processed at the New Orleans Induction Station. Although the number of examinees in our series is only about one third less than in the survey reported by Blotner,² the number of men with diabetes in our group is much smaller. In our group there were only 37 cases of glycosuria, and of these only 9 appeared to be true diabetes mellitus. Thus our group showed a rate of 1.15 per thousand for glycosuria and slightly less than 0.3 per thousand for diabetes.

This is in wide variance with the figures presented by Blotner and his co-workers,² who found among their 45,650 selectees 367 cases of glycosuria, or 8 per thousand; and of these more than half, or 208, were cases of diabetes (4.5 per thousand). This, as was pointed out in the editorial,¹ is a high rate in both categories. Our rate for glycosuria of 1.15 per thou-

Major Spellberg is instructor of medicine at the University of Illinois College of Medicine on leave of absence.

sand compares favorably with rates reported by other observers. Sydenstricker and Britten³ reported that glycosuria in the age group 20 to 24 occurs at the rate of 1.1 per thousand, increasing to 2.2 per thousand in the group 30 to 34. Dublin and his co-workers⁴ found that frank glycosuria under 25 years of age occurs at the rate of 1 per thousand, going up to 3 per thousand between 25 and 34 years of age. In a mixed group of insurance applicants reported by Marble⁵ the incidence of glycosuria was found to be 2.8 per thousand. However, our diabetic rate of 0.28 per thousand is a good deal lower than the national health survey rate of 0.6 per thousand in the age group 15 to 24 and 0.9 per thousand in the age group 25 to 34.

Although the number of diabetic individuals in our group is small, the group of selectees is sufficiently large to make our statistics of some significance. The question that immediately arises is Why is there so much discrepancy between our findings and those of the New England workers? Our group differs in several respects from the other group. All these differences would tend to diminish the incidence of diabetes.

The two groups differ slightly in age. The selectees we studied were examined in 1944, when very few men over 35 years of age were inducted. Thus our group is practically confined to the age group 18 to 35. The New England studies were reported in 1943 and admittedly included age groups up to 45. That the incidence of diabetes increases rapidly with increasing age is well established. Thus, Joslin, Dublin and Marks⁶ found that diabetes is nearly three times more common in the age group 40 to 45 than it is in the younger group of 20 to 39. Sydenstricker and Britten³ also noted a tripling of incidence in the older group of 40 to 45 as compared with the younger group of 25 to 29.

The incidence of diabetes varies widely in its geographic distribution. The lowest rate in the United States is found in the rural South and the highest in the urban and highly industrialized Eastern seaboard and New England states. Joslin and his co-workers⁶ found that the mortality from diabetes in the white population of Rhode Island was 26.9 per hundred thousand and of New York 26.7 per hundred thousand, while in Louisiana the mortality was only 13.2 per hundred thousand and in Arkansas 8.3 per hundred thousand. Himsworth⁷ also points out that the diabetic death rate is twice as high in the North as it is in the South and ascribes this to the difference in diet.

Race is also an important factor in the incidence of diabetes. It is less common among Negroes both in the North and in the South as compared with the white population in these regions. Its incidence is lower in the Southern than in the Northern Negro.⁸ One third of our group of selectees were Negroes and hence would contribute to the lowering of the incidence of this disease in our group.

Recent publications suggest that diabetes is an uncommon factor for rejection for military service. Rowntree,⁹ reporting on the estimated causes for rejection of selectees in the age group 18 to 37, does not mention diabetes in his statistics. Diabetes is probably included under the heading of "Endocrine Disorders," which is responsible for 1 per cent of rejections, or under the heading of "Other Medical Defects," with a rejection rate of 0.6 per cent. Likewise, in the report by Gallagher and Brouha¹⁰ diabetes is not mentioned in the enumeration of various causes for rejection.

Another and perhaps very important cause for variation of the different statistics dealing with the incidence of diabetes depends on the criteria of diagnosis. In the diagnosis of the mild and previously undetected disease, which is usually unaccompanied by symptoms, the glucose tolerance test may be the sole criterion. There are several methods of performing this test. The boundary line between the normal and the abnormal curve is not sharp, varies with different authorities and at best is beset by many pitfalls. Finally, even a definitely abnormal and diabetic-like curve may not be due to diabetes.

In the most commonly used test, in which 100 Gm. of glucose is administered orally, the "normal" individual shows a maximum rise of the blood sugar to between 170 and 180 mg. per hundred cubic centimeters and at two hours a return to the fasting level.¹¹ The fasting blood sugar should be between 80 and 120 mg. per hundred cubic centimeters of blood. Joslin¹¹ places the greatest emphasis on the rise of the blood sugar, stating that a value of over 170 mg. per hundred cubic centimeters ordinarily justifies a diagnosis of diabetes. Marble¹¹ adds that a return to the fasting level in two hours is an important criterion. But what if the fasting level is 70 to 80 mg. per hundred cubic centimeters and a two hour value is 10 to 15 mg. above this? Are we justified in calling such a curve diabetic or even pathologic? John¹² relaxes the latter criterion somewhat by assuming that a return of blood sugar to 120 mg. per hundred cubic centimeters of blood or lower in two and one-half hours can be considered within limits.

No clinical test can be interpreted too strictly and specific diagnostic implications made therefrom. A glucose tolerance curve is no exception. Many pathologic and physiologic states can have a profound influence on blood sugar and carbohydrate tolerance. Differences in the rate of intestinal absorption will have an influence on the oral glucose tolerance test. Malfunction of other endocrine glands (besides the pancreas) and the liver¹³ can produce diabetic-like glucose tolerance curves. Obesity may be accompanied by disturbed carbohydrate tolerance.¹⁴ The influence of emotions¹⁵ and previous diet¹⁶ on the glucose tolerance curve are well known.

Antecedent diet is probably the commonest disturbing factor. Since dietary histories are notoriously unreliable, it has been recommended to place the candidate on a high carbohydrate diet before the tolerance test is performed. This is quite impractical, especially when larger groups of individuals are studied, as in

TABLE 1.—Normal *Exton-Rose* Tests

Case	Fasting Blood Sugar	½ Hour	1 Hour
1.	81	129	138

19	105	146	125

military practice. The "Exton-Rose" test,¹⁷ in which two 50 Gm. doses of glucose are administered at half hour intervals, was supposed to obviate this difficulty. The first dose presumably primed the carbohydrate regulating mechanism so that the second dose of glucose produced a drop or only a slight rise in the blood sugar. Thus, according to the early standards laid down by Exton and Rose,¹⁷ a normal curve should include (1) normal fasting blood sugar, (2) one-half hour after the first dose of glucose a rise in blood sugar not to exceed 75 mg. per hundred cubic centimeters of blood, and (3) one-half hour after the second dose of glucose a rise in blood sugar not to exceed 5 mg. per hundred cubic centimeters of blood. Wayburn and Gray¹⁸ agreed that this test obviates the influence of previous diets on the glucose tolerance curve but used a two hour determination to distinguish the severe cases of disturbed carbohydrate metabolism.

Many observers, however, disagree with the conception that previous diet had no influence on the "Exton-Rose" curve and also the standard of normality set down by Exton and Rose.¹⁷ Thus, Sweeney and his co-workers¹⁹ as well as Langner and his co-workers²⁰ concluded that a high fat diet would distort the Exton-Rose curve to the diabetic side. The latter workers²⁰ also considered a blood sugar of over 140 either at the half-hour or one hour period as abnormal. Langner and Dewees²¹ concluded that the original interpretation as set down by Exton and Rose¹⁷ is too rigid and would label many normal individuals diabetic. They agreed with Matthews and his co-workers²² that the

emphasis on the rise between the first and the second dose of glucose is not justified and that if the one hour value does not exceed 160 mg. per hundred cubic centimeters of blood the response should be considered normal. If this value is 160 to 180 mg. of sugar per hundred cubic centimeters of blood it should be called borderline, but if over 180 it should be considered as definitely diabetic. Gould and his co-workers²³ allow for a total rise of less than 80 mg. of glucose per hundred cubic centimeters of blood but contend that in a normal individual the one-half hour rise should be under 50 mg. and the one hour rise under 30 mg. per hundred cubic centimeters of blood. Thus it can be readily seen that the criteria of normality vary widely with this test.

We used the "Exton-Rose" test first on all our patients. This procedure has technical advantages which are helpful in surveys of large numbers of patients, since only three blood sugar determinations are required and the test lasts only one hour. If the rigid criteria of Exton and Rose are applied, perhaps with slight modifications, all diabetic persons are immediately ruled out by a normal response. Nineteen of our 37 cases (table 1) studied for glycosuria gave a normal Exton-Rose response. Fasting blood sugars varied between 80 and 110 mg. per hundred cubic centimeters of blood and all except three had a blood sugar below 100. The greatest rise of blood sugar after the first dose of dextrose was 65 mg. per hundred cubic centimeters of blood. The blood sugar after the second dose of glucose showed a fall in 12 of the 19 cases. The other 7 showed a rise of 5 to 20 mg. of dextrose per hundred cubic centimeters of blood. One 15 and one 20 mg. rise were included in this normal group, although it is above the maximum rise permitted by Exton and Rose, because these occurred in persons with essentially low blood sugar values. The 20 mg rise (case 18, table 1), which was from 105 to 125 mg., was the highest, and the 15 mg rise (case 8, table 1), in which the highest blood sugar value was 138 mg. per hundred cubic centimeters of blood.

TABLE 2.—Abnormal *Exton-Rose* and Normal Three Hour Glucose Tolerance Tests

Case	Abnormal Exton Rose Tests			Normal Three Hour Glucose Tolerance Tests				
	Blood Sugar per 100 Cc of Blood			Blood sugar per 100 Cc of Blood				
	Fast mg	½ Hour	1 Hour	Fast mg	½ Hour	1 Hour	2 Hours	3 Hours
1	101	123	154	95	117	111	90	80
2	94	140	167	83	129	135	61	80
3	86	125	142	80	100	133	106	76
4	93	110	148	88	114	101	92	80
5	72	121	140	80	120	95	92	77
6	100	183	145	102	180	133	91	68
7	112	210	182					
	101	139	152	106	110	111	108	80
8	91	212	160	96	133	167	98	83
9	106	215	235	102	174	143	76	74
10	92	144	222	100	166	160	111	66

When the Exton-Rose curve gave "abnormal" values another glucose tolerance test was done the following day, using 100 Gm. of glucose in one dose and doing blood sugar determinations for three hours. Ten of our group of glycosurias gave abnormal Exton-Rose curves followed by a normal three hour glucose tolerance curve

(table 2). The first five of these ten Exton-Rose curves would have been considered normal by the more liberal interpretation of this test.²⁴ This again shows that the criteria of Exton and Rose would label some normal persons diabetic. The last five "Exton-Rose" tests (table 2) are definitely abnormal by all criteria,

cubic centimeters of blood with a return to normal fasting level at the end of two hours and only 66 mg. at three hours.

The 9 patients with diabetes (table 3) showed completely abnormal glucose tolerance tests both by the Exton-Rose curve and by the three hour test. The fasting blood sugar was above 120 mg. per hundred cubic centimeters in only 2 individuals. The one hour value in the Exton-Rose curve was higher than the

Chart 1.—Exton-Rose and three hour tests in case 7, table 2.

and if we had stopped here a diagnosis of diabetes would have been made in these cases. The three hour glucose tolerance tests, however, done the following day were normal in all these cases. The maximum height of the blood sugar in these three hour curves was 180 mg. per hundred cubic centimeters of blood occurring only in 1 case. A level of 174 mg. per hundred cubic centimeters of blood was recorded in another case. The rest showed all values below 170 mg. The blood sugar returned to a normal fasting level in two hours and in most was below the control value of that individual.

The change of the glucose tolerance curve from one day to the next was quite remarkable. Case 7, table 2, is especially noteworthy. The first Exton-Rose curve showed a fairly high normal fasting blood sugar of 112 mg. of dextrose per hundred cubic centimeters of blood, followed by a rise of nearly 100 mg. after the first dose of glucose. Although a fall of blood sugar occurred after the second dose of glucose, this value was still over 180 mg. The next day the fasting blood sugar was lower; the first rise was only 38 mg. per hundred cubic centimeters of blood. After the second dose of glucose there was a rise of only 13 mg., so although according to the standards of Exton and Rose¹⁷ this is still an abnormal response, according to all the other interpretations²⁵ this is to be considered normal. On the third day a three hour test yielded a flat curve with a fall of blood sugar at three hours to a level 26 mg. below fasting (chart 1). Another case worth mentioning is case 10, table 2 (chart 2). The Exton-Rose curve again is abnormal according to all criteria, with the one hour value being 222 mg. of glucose per hundred cubic centimeters of blood. The three hour test the following day was normal in all respects, the maximum rise being to 166 mg. of sugar per hundred

TABLE 3.—Glucose Tolerance Tests in Diabetic Patients

Case	Exton-Rose			Three Hour Test				
	Fasting	1/2 Hour	1 Hour	Fasting	1/2 Hour	1 Hour	2 Hours	3 Hours
1	120	206	206	118	200	232	200	98
2	180	206	276					
3	122	216	302	119	232	332	338	208
4	102	144	238	97	209	200	106	80
5	97	192	250	98	195	250	206	88
6	94	222	298	100	215	245	160	130
7	86	125	166	93	122	170	174	108
8	86	105	181	89	160	200	140	67
9	103	154	247	114	216	280	278	190

half-hour value in all but 1 case. In the latter the two values were the same. The one hour value was above 200 in all but 2, and in 4 it was 250 mg. per hundred cubic centimeters of blood or higher. In the three hour test the return of the blood sugar to fasting level was definitely slow. Only 1 case (case 4, table 3) showed a normal value at two hours. In 3 patients the three hour value was above normal. It seems that the rate of return of the blood sugar to a fasting level is a more certain criterion of diabetes than the height of the blood sugar.

Chart 2.—Exton-Rose and three hour tests in case 10, table 2.

Two cases in this group (table 3) showed borderline curves. Case 7, table 3, had a borderline Exton-Rose curve. The three hour test showed a slow rise in blood sugar and the half hour value was only 122 mg. of glucose per hundred cubic centimeters of blood, but the two hour value was 174 mg. A temporary disturbance of intestinal motility, such as duodenal or pyloric spasm, may have interfered with absorption; hence the slow

24. Langner and Dewees.²¹ Matthews, Magath and Berkson.²²
25. Langner and Dewees.²¹ Matthews, Magath and Berkson.²² Gould, Altshuler and Mellen.²³

rise in blood sugar and the hyperglycemia at two hours. Case 4 had a grossly abnormal Exton-Rose curve. The only abnormality, however, in the three hour curve was the rise of the blood sugar to 209 mg. per hundred cubic centimeters of blood. The return to a normal value occurred in two hours. A curve of this type could conceivably be due to rapid absorption from the intestine and some delay in glycogenesis by a mildly disturbed liver function.

The phenomenon shown in table 2 of a highly abnormal "Exton-Rose" test followed the next day by a perfectly normal three hour glucose tolerance curve is of great significance. It emphasizes the danger of establishing the diagnosis of diabetes on the basis of a single glucose tolerance curve. Unless the first glucose tolerance test is highly abnormal, that is, one which shows a very great rise of blood sugar (above 250 mg.), failure to return to the fasting level in three hours (three hour curve) and a fasting level above 120 mg., another glucose tolerance curve should be done the following day. The first abnormal glucose tolerance response may be dependent on the fact that the patient subsisted on a high fat diet. The administration of the hundred grams of glucose in the first test stimulates the patient's carbohydrate regulating mechanism and results in a normal glucose tolerance curve the following day. This apparently occurred in our case in table 2. The one hour two dose test may be preferable as the first test because of its technical advantages. If this test is normal it may be safely concluded that diabetes mellitus is ruled out.

Other factors may influence the oral glucose tolerance, such as rate of intestinal absorption and motility. Many factors may disturb carbohydrate metabolism¹³ besides true diabetes, and some of these disturbances may be transient. Many nondiabetic persons will be labeled diabetic if a strict interpretation of one glucose tolerance test is used as the sole basis for diagnosis.

SUMMARY AND CONCLUSIONS

1. Of 32,033 inductees examined in New Orleans, 37 had glycosuria.
2. Only 9, or 0.28 per thousand, had diabetes mellitus.
3. The one hour two dose (Exton-Rose) glucose tolerance curve is useful in the routine study of large groups of individuals.
4. One abnormal glucose tolerance curve may be due to a previously abnormal diet and should not serve as a basis for a positive diagnosis of diabetes.
5. If another dextrose tolerance curve is done the following day, it may be completely normal, as found in 10 of our cases.
6. The diagnosis of diabetes on the basis of one mildly abnormal glucose tolerance test is unjustified.

Humane Education for Medicine.—A humane education is an invaluable asset to any youth embarking on the study of medicine. I am aware that I raise the banner of a forsaken cause when I say this; but nevertheless, twenty-five years of clinical teaching have fully persuaded me that, when I find a clinical clerk who can stand up and read at a ward visit a case history that is a well ordered, lucid and fluently expressed account of the patient and his situation, that student will almost invariably be found to have had a sound education and not a mere course of instruction of the polytechnic order, a utility education.—Walshe, F. M. R.: *The Integration of Medicine*, Brit M. J., May 26, 1945.

AEROSOL PENICILLIN IN GENERAL PRACTICE

HERBERT N. VERMILYE, M.D.
FOREST HILLS, N. Y.

My object in this presentation is to demonstrate the advantages of the Barach aerosol penicillin method¹ as an effective, inexpensive means of treatment which eliminates some of the present difficulties of penicillin administration. It makes penicillin therapy readily available to the general practitioner in the office and to the patient in the home. The particular value of the technic in upper respiratory infections is emphasized, since a large proportion of conditions for which penicillin is required in general practice are the acute bacterial invasions and chronic bacterial infections of the upper respiratory tract which develop into parasitic states.² In many of these cases it appears to be more efficient than the parenteral method.

The preeminent value of parenteral penicillin therapy in many infections and its freedom from severe reactions have now been established by a mass of clinical evidence. The only real disadvantage found in penicillin treatment has been the necessity for frequent intramuscular injections or continuous intravenous administration. It is generally considered that hospitalization and continual medical supervision and nursing care are essential. However, various technics are being tested by means of which adequately bacteriostatic levels of penicillin may be maintained in the body with less frequent injection or by oral administration.³

A number of investigators have reported the therapeutic value of the sulfonamides in respiratory infections when administered by inhalation of vaporized solutions. A comparable technic of administering penicillin has been described by Barach,¹ Bryson,⁴ and Knott and Clark.⁵ These papers, especially that of Barach, should be consulted for a full description of the various steps by which a satisfactory technic for inhaling penicillin solution was developed. The preliminary investigations⁶ showed that a highly concentrated penicillin solution could be nebulized and inhaled as a mist without diminishing its potency; Knott and Clark⁵ found that

1 Barach, Alvan L., Silberstein, Frederick H.; Oppenheimer, Enid T., Hunter, Thomas, and Soroka, Max. Inhalation of Penicillin Aerosol in Patients with Bronchial Asthma, Chronic Bronchitis, Bronchiectasis and Lung Abscess. Preliminary Report, *Ann Int Med* 22:485 (April) 1945.

2 The symptoms caused by chronic infection with a specific organism are apparently not yet widely recognized, although such parasitic bacterial states may cause a diversity of symptoms in tissues other than the upper respiratory tract. There is need of a definitive term for such chronic infections, one more exact than "focal infection" and one which implies a balance between the resistance factors of the host and the adaptation of the bacterial cells to these resistance factors. Colin MacLeod (personal communication) observed patients in whom specific pneumococcus types persisted for over ten years. From 1 patient in the author's series MacLeod repeatedly cultured pneumococcus types XIII and XIX over a period of six years. Although there were no extrinsic allergies, many allergic symptoms developed which responded dramatically to aerosol penicillin, as they did in other similar cases. R. A. Goodwin Jr., Clare Wilcox and Maxwell Finland (Persistence of Pneumococci in Sulfonamide Treated Cases of Pneumonia, *Am. J. M. Sc.* 209:629 (1945)) describe the persistence of pneumococci for shorter periods after sulfonamide therapy. Homer Swift (personal communication) and Norman Plummer, D. R. Duerschner, H. D. Warren, F. T. Roghano and R. A. Sloan (Penicillin Therapy in Hemolytic Streptococcal Pharyngitis and Tonsillitis, *J. A. M. A.* 127:369 [Feb 17] 1945) state that persistent infections due to certain Lancefield types of streptococci should be treated before complications develop. In this group of cases several persistent group A streptococcal infections involving the upper respiratory tissues appear to have been eliminated by aerosol penicillin therapy when parenteral penicillin failed.

penicillin dispersed as an aerosol in a room was fully active for at least ninety minutes. No significant differences could be detected in microscopic lung sections of rats which had been given inhalations of penicillin, neosynephrin, sulfathiazole, sulmeprin, 20 per cent potassium iodide solution and 2.5 per cent sulfadiazine in ethanolamine solution, as compared with those given saline inhalations or no treatment.¹ Thus, the deposition of penicillin in the lung tissues by aerosolization is apparently safe.

Inhalation of sodium penicillin by nearly all patients was carried out without by-effects. The calcium salt of penicillin was later found to produce a superior aerosol. It was also preferred by patients because it had less odor and was much less likely to cause coughing. The minor side reactions observed by Barach are discussed later.

One objective of the aerosol technic is to bring the highly antibiotic penicillin into closer contact with the actual infecting organisms; this is analogous to the injection of penicillin solution into empyema cavities or into the spinal fluid in meningitis. It is thus evident that the local application and concentration of penicillin at the site of infection are more significant than the blood level or the urinary excretion of the drug. Both of these values are measures of the absorption of penicillin and not actual indications of its clinical effectiveness, at least so far as topical application is concerned. It is of interest to note, however, that penicillin is readily absorbed from the lungs; high blood levels are attained when long slow breathing, with a pause before exhaling, is practiced. Blood concentrations of from 0.01 to 0.04 unit per cubic centimeter and as high as 0.18 unit were found during the first fifteen minutes to one hour after inhalation of from 20,000 to 70,000 units.¹ In the present investigation, when the new type of nebulizer and cut off valve were used, a 50 pound (23 Kg.) boy had a blood level of 0.02 unit per cubic centimeter one hour after inhaling 7,000 units of penicillin. The blood concentration in an asthmatic man weighing 180 pounds (82 Kg.) was 0.05 unit per cubic centimeter one-half hour after a 20,000 unit inhalation. Similar concentrations were found in many other cases. Actually any desired blood level of penicillin may be obtained by the aerosol method if more frequent intermittent or continuous inhalation through an oxygen mask is employed.

The percentage recovery of penicillin in the urine varies. Using a less refined nebulizer, from 10 to 20 per cent of the total dose of penicillin was recovered in twenty-four hours in Barach's reported cases;¹ using more efficient apparatus the recovery ranged from 30 to 50 per cent.⁷ With slow, deep inhalations that are held for several seconds, urinary recovery is greater because the blood concentration is generally higher.

TECHNIC AND DOSAGE

The apparatus required for the nebulization of penicillin is available from most oxygen equipment companies and may be obtained for about \$10 if a small portable oxygen tank is used. A physician with ten or more outfits can treat at least 20 cases a week without nursing assistance, once the method of using the apparatus is understood by the patient. Outfits may be placed in the home for use of patients too ill to come to the office.

The apparatus now used consists of an oxygen tank equipped with a valve for controlling the flow of oxygen

at about 4 liters per minute. (Optionally, another automatic valve may also be used to cut off the flow of oxygen except during inspiration.) Oxygen flows to the Vaponephrin nebulizer by tubing attached to the intake arm. A Y tube is inserted at some point in the rubber tubing, leaving one arm of the Y free. The aperture at the top of the nebulizer is left open. An improvement consists in the attachment of a 1,000 cc. bulb with a hole at the top to the original nebulizer at the carburetor. This permits some economy in the use of penicillin, but it is not essential. This apparatus has been found satisfactory. Barach describes some modifications of it in his report.

Sodium penicillin⁸ (or the calcium salt) is prepared by dissolving the drug in sterile isotonic solution of sodium chloride in such amounts that from 0.5 to 1 cc. contains the desired dosage. As a rule the dose in adults is 25,000 in 1 cc., although 50,000 units per cubic centimeter is frequently used. After nebulization of the penicillin solution, 0.5 cc. of isotonic solution of sodium chloride is injected into the nebulizer and also inhaled, thus avoiding waste of penicillin. (An aqueous solution of penicillin is irritating when inhaled. The lighter colored preparations are preferred by patients because they taste better.) In cases of sinusitis, neosynephrin or priline is used as nose drops to open the sinuses; in asthma and other conditions causing bronchospasm 0.5 cc. of 0.25 per cent neosynephrine may first be inhaled from the nebulizer so that penicillin may be more effectively brought into contact with the desired areas. The nebulizer must be rinsed out before subsequent use with penicillin. In ambulatory patients, office treatments are usually given three to five times daily at three or four hour intervals. Medication may be continued during the night by patients having the apparatus at home. In conditions involving local accumulations of pus it may be advisable to reinforce the inhalations by injections into the involved area, as in empyema. A nose and throat spray containing 500 units per cubic centimeter is sometimes used at home.

The technic of inhalation consists in placing the mouthpiece of the nebulizer in the mouth or nose and inhaling slowly and deeply, then holding the breath for several seconds to permit deposition of the penicillin particles and to prevent its loss during expiration, and then exhaling. Since the flow of oxygen passes out through the open arm of the Y tube, little oxygen enters the nebulizer until the finger is placed on this arm. The actions of breathing and diverting oxygen into the nebulizer are synchronized. With the nebulizer well within the mouth and the lungs empty, a finger of the nurse or patient is placed on the Y tube opening (thus starting immediate nebulization) and the patient at the same time begins a slow inspiration. Before inspiration is quite complete, the finger is removed from the Y tube, inspiration is completed and held for several seconds, and then expiration is allowed. With this technic little or no vapor can be seen on exhalation. Some patients cannot breathe deeply, but holding the breath will help deposit penicillin in the respiratory tissues. Part of the penicillin solution is also inhaled through the nose; the side of the nose not in use must be closed by finger pressure. The method of inhalation is readily learned by patients and can be carried out unattended save for preliminary instruction. Children as young as 2 years have been successfully given courses of inhalation.

7. Barach, Alvan L.: Personal communication to the author.

8. Schenley Laboratories, E. R. Squibb & Sons and Winthrop Chemical Company, Inc., provided the penicillin.

A modification of this technic consists in attaching a positive pressure oxygen mask to the nebulizer containing penicillin solution. This may be utilized routinely for babies, or for adults for whom the continuous inhalation of oxygen is also desired to prevent pulmonary edema.

The blood concentration can be maintained at any desired level. Barach found blood concentrations as high as 0.4 unit per cubic centimeter using a single inhalation of 100,000 units. Continuous inhalation would therefore seem to be an adequate substitute for the unpleasant continuous intravenous drip method of administration. The blood concentration may be maintained at an effective level by varying the strength of the penicillin solution to be nebulized and the rate of nebulization.

Penicillin may also be nebulized through a catheter directly into infected antrums or sphenoid sinuses after preliminary evacuation and irrigation. For this purpose the upper opening of the nebulizer must be closed by a cork or the finger. No irritation is caused by an aerosol of a solution containing 20,000 units of penicillin per cubic centimeter.

PROCEDURE

Penicillin therapy should be considered as only one factor in the general treatment of the patient. Most penicillin failures, aside from its use against nonsusceptible organisms, occur when the physician fails to recognize and treat such conditions as medical shock, diabetes mellitus, pernicious anemia, achylia gastrica, severe or even mild nutritional failures due to prolonged malnutrition or anorexia and vomiting, congenital conditions leading to rickets or conditions of the gallbladder and bile ducts causing depletion of the bile-soluble vitamins, and allergies due to pollens, foods and other irritants. Penicillin has been found to act more effectively in patients who are in or are brought into a state of adequate nutrition. Therefore supplementary treatment with various vitamins and crude liver extract (Campolon) is often employed.⁹

The procedure in this investigation has been to treat all underlying factors by standard available methods along with aerosol penicillin. Before beginning treatment a thorough physical examination is made. Wherever possible, cultures¹⁰ are taken from the nose, throat and sputum and cultured in nutrient-blood broth and mouse peritoneum. Pneumococci are typed by the direct method and hemolytic streptococci¹¹ by the Swift-Wilson-Lancefield technic. Determinations of the blood count, hemoglobin and erythrocyte sedimentation rate and routine urinalysis are usually carried out. Psychosomatic evaluation of the patient is important. Roentgenograms of the lungs and sinuses are obtained when indicated. In many cases special tests such as those for pollens, danders, feathers and house dust are required, and nonallergic diets must be provided to eliminate food allergies. Electrocardiograms, renal and liver function tests as well as chemical examination of the blood and urine may be necessary. Foci of infection, such as bad teeth and useless tonsils, should be removed.

9. Claassen (in Harvey Lectures, 1941-1943, Lancaster, Pa., Science Press, 1943, vol. 38, p. 37.) reported that patients with chronic infections have very low levels of plasma vitamin A, and conversely that the resistance factors of the host are lowered in any condition in which the vitamin A saturation of the liver, plasma and tissues is depleted. These observations have been confirmed by other investigators.

10. Eli Gardiner, Ph.D., aided materially in the bacteriologic procedures and carried out the streptococcus typing.

11. E. R. Squibb & Sons supplied the hemolytic streptococcus typing serums.

TYPES OF CASES SUITABLE FOR AEROSOL THERAPY

Over 200 patients with various upper respiratory conditions, or manifesting allergic reactions to an upper respiratory infection, have been treated with aerosol penicillin. Since a full report of these highly diversified cases would not be practical for presentation at one time, only the more common manifestations of upper respiratory infections are reported here. Since it may be of interest to indicate the variety of cases successfully treated by aerosol penicillin, the following classification is presented. It must be borne in mind that such bizarre complaints as migraine, eczema, rosacea, duodenal pain, allergic colitis, extreme fatigue and even mild psychoneurotic symptoms may in fact be either due to, or aggravated by, allergy to the presence of a mild chronic or acute upper respiratory infection.

I. Acute primary invasions of the respiratory tissues with and without pneumonitis:

- A. Pneumococcus types.
- B. Hemolytic streptococcus and staphylococcus types.
- C. Virus types with secondary invasions of hemolytic streptococci and staphylococci and the nonhemolytic streptococcus MG group.

II. Persistent bacterial infections of the upper respiratory tract due to pneumococci (thirty-five types), hemolytic streptococci (forty types) and staphylococci, with acute pneumonic episodes without allergic manifestations.

III. Persistent bacterial infections of the upper respiratory tract which develop into bacterial allergies in the constitutionally nonallergic patient.

IV. Upper respiratory bacterial infections which develop into bacterial allergies in individuals who have an allergic type of constitution in combination with other extrinsic allergies:

- A. Sinobronchitis.
- B. Eczema.
- C. Asthma.
- D. Migraine:
 1. With headache as the predominant symptom.
 2. With hemicrania and simulated trifacial neuralgia, with or without biliary viscerospasm.
 3. Intestinal crises without headache.
 4. Psychotic or psychosomatic types.

V. Chronic upper respiratory bacterial infections with acute fatigue persisting for years in allergic and nonallergic subjects.

VI. Acute and chronic upper respiratory bacterial infections which lead to glomerulonephritis and hypertension, sinusitis with nephrosis, and myocarditis with and without hypertension.

PNEUMONITIS

The use of aerosol penicillin in the treatment of pneumonitis is entirely logical, since it brings the drug into very close contact with the infecting organisms. It is true, of course, that penicillin by parenteral routes has proved very effective in pneumonitis due to many susceptible bacteria. However, the applicability of aerosol penicillin to home use without trained assistance is of definite advantage, in addition to the fact that the highest concentration of penicillin is attained in the diseased tissues. The usual treatment of pneumonitis in the adult consists in the inhalation of 50,000 units every three or four hours or a continuous inhalation of nebulized penicillin through the Barach positive pressure oxygen mask. In severe cases a combination of aerosol and parenteral penicillin has been found more effective, inhalations and injections being given alternately at two hour intervals. Although interstitial virus pneumonitis does not in itself respond to penicillin, the use of positive pressure oxygen inhalation helps prevent pulmonary edema, and penicillin eradicates the secondary invaders, pneumococci, hemolytic streptococci and hemolytic

staphylococci, which are usually considered to be the actual cause of death in virus pneumonitis.¹² The course of the disease is shortened and disability is less severe.

It is advisable to take cultures of the sputum and nasopharynx to determine the infecting organism before penicillin therapy is started. Certain bacteria, such as *Hemophilus influenzae* (Pfeiffer's bacillus) and some strains of *Staphylococcus aureus*, are resistant to the action of penicillin but may respond to sulfonamides. The amount of penicillin required in pneumonitis depends to some extent on the infecting agent. Pneumococci are more sensitive on the whole than streptococci or staphylococci; the latter often require very large doses.

Over 30 cases of pneumonitis due to various organisms have been successfully treated with aerosol penicillin alone or in conjunction with parenteral penicillin. Examples of acute and chronic pneumonitis are given:

Acute pneumonitis. M. McG., a boy aged 14 years, was brought to the office after being sent home from boarding school. He was nervous, "jittery" and apprehensive and had a dry irritating cough. His temperature was 102 F. Physical examination showed moderate diffuse pharyngitis and very little postnasal drip or drainage from the sinuses. There was a moderate amount of dullness over the right lower lobe posteriorly and many fine moist rales. The leukocyte count was 28,000, 85 per cent polymorphonuclears, the sedimentation rate was increased, and the hemoglobin was 17.5 mg. per hundred cubic centimeters. Nasopharyngeal cultures and sputum were secured for study; these subsequently showed pneumococcus type XX. He was given an inhalation of 40,000 units of penicillin and taken home. Three hours later when he returned for another treatment he was much improved. Four inhalations were given that day and one intramuscular injection of 25,000 units at 2 a. m. On the second day the patient felt so well that he wanted to walk home. Treatment was continued for a week. The chest signs disappeared completely by the third day; he was lively and had lost all nervousness and apprehension. During the next two weeks an inhalation was given in the morning and evening. Three days after penicillin was stopped no pneumococci could be found by culture.

This boy was seen at the onset of acute pneumococcal pneumonitis. Early diagnosis and aerosol penicillin treatment were responsible for checking the spread of infection at once. Moreover, the boy was in an excellent frame of mind after the first day and was up and about most of the time. This immediate response and relative feeling of well-being are characteristic of aerosol penicillin therapy in pneumonitis and have been noted repeatedly. In fact, patients can be made to understand only with difficulty how ill they were or might have been.

Pneumonitis with allergies to persistent pneumococcal infection. H. S., a man aged 45, was first seen with pneumonitis. The leukocyte count was 12,000, 75 per cent polymorphonuclears, and the sedimentation rate (Westergren) 38 mm. per hour. Type VII pneumococcus was demonstrated by direct typing. After treatment for three weeks with 5 Gm. of sulfadiazine daily and frequent injections of crude liver extract, the patient still had disabling symptoms consisting of profuse sweating on exertion, nervousness, attacks of acute abdominal pain and occasional loose watery stools. Most of these symptoms, which persisted for two months, could be classified as allergic reactions to the persistent type VII pneumococcus infection. Roentgenograms revealed resolving pneumonitis at the apex of the right lung. No extrinsic allergies could be found.

When aerosol penicillin became available, the chronic pneumococcal infection was treated with aerosol penicillin, 20,000 units

four times a day for three days, followed by 30,000 units once a day for a week while at work. After the first four inhalations the patient felt well and his symptoms appeared to be eliminated. The cultures were negative after treatment was stopped. He has continued in excellent health.

It is apparent that in this case aerosol penicillin cured a chronic pneumococcal infection that was resistant to sulfadiazine. Had the aerosol penicillin technique been available earlier, this patient might have been spared months of disability.

It may be of interest to note that, in the epidemic of an unclassified virus disease of the upper respiratory tract during the late winter months, aerosol penicillin was used to good effect. While the virus infection itself was probably not influenced by the drug, the patients frequently were definitely benefited because secondary bacterial infections did not arise to complicate the original disease. Many patients appeared to be well after treatment for one or two days although penicillin was continued for about five days. Perhaps one factor in the rapid recoveries was the general feeling of well being and the increased appetite which commonly accompany aerosol penicillin therapy. Similarly the duration of colds has been repeatedly shortened because of the elimination of secondary bacterial invasions. This was noted especially in patients who usually develop a heavy cough with much sputum a few days after the first symptoms of the cold appear.

TONSILLITIS, SINUSITIS AND SINOBRONCHITIS

Tonsillitis, sinusitis and sinobronchitis are three conditions forming a rather large proportion of cases in any general practice, particularly in the New York City area. Sulfonamides have all too often been of little value, no matter how freely they have been used. As far as parenteral penicillin therapy is concerned, acute sinusitis has been reported to yield to penicillin fairly regularly, but chronic tonsillitis and chronic sinusitis have all too often resisted its action;¹³ administration locally by drops, sprays and irrigations may be of limited value.¹⁴ Similarly the results of parenteral penicillin therapy in sinobronchitis have not been uniformly satisfactory. Experience with aerosol penicillin has, however, been far more encouraging, perhaps because the drug is deposited at the sites of infection.

It is important in treating sinusitis to precede the use of aerosol penicillin with application of a vasoconstrictor in the form of drops or a spray in the nose. For the treatment of sinusitis the nebulizer is inserted into the nares through which penicillin solution is inhaled. Often it has been found advisable to continue single daily prophylactic inhalations for a week or so after the infection is apparently controlled. A penicillin nose spray is frequently employed in the evening at home during the acute phase. In some cases of chronic suppuration of the sphenoids or antrums it is necessary to wash out the pus by catheter and then introduce 20,000 units of penicillin mist through the catheter. The mist is much less irritating than a 20,000 unit solution of penicillin and far more efficient than a solution of 250 units per cubic centimeter. If the nasal structure does not cause too much anatomic blockage, aerosol penicillin readily penetrates into the ethmoid cells after shrinkage with praline. When polyps are present, aerosol penicillin acts better after their removal.

Tonsillitis. L. B., a man aged 32, was first seen at the office on February 23 complaining of acute epigastric pain which had been treated unsuccessfully for five weeks by antacids and a Sippy diet. He had a history of indigestion for years and repeated attacks of tonsillitis, the latest three months previously. The patient was obviously suffering acute pain, probably due to pylorospasm. Tenderness was present only over the epigastrium. The tonsils were enlarged, and purulent exudate could be expressed. Other abnormal findings were a blood pressure of 150/100 lying and 120/80 standing; a leukocyte count of 14,000 with 78 per cent polymorphonuclears; sedimentation rate (Westergren) 28 mm. in one hour. A throat culture taken at this time subsequently showed a nonhemolytic streptococcus and *Streptococcus viridans*. At later visits the electrocardiogram was normal; roentgenographic examination of the heart and lungs was negative. The first attempt to obtain roentgenograms of the gastrointestinal tract failed because duodenal contractions prevented the passage of barium. Three days later, after an injection of isonipecaine (Demerol), barium passed into the duodenum without difficulty. No abnormality could be visualized. The gastric analysis after histamine stimulation was slightly above normal.

Immediate relief of the severe pain was obtained with 50 mg. of isonipecaine given hypodermically. This was indicative, since isonipecaine relieves vagotonia and viscerospasm similarly to its effect on the vagotonia of asthma. A tentative diagnosis of gastrointestinal allergy to the tonsillar infection warranted a course of aerosol penicillin, 30,000 units every four hours. After the third inhalation, the pain from viscerospasm was completely absent. On the third day the patient had a single inhalation and then went to work, not returning until 8 o'clock in the evening. Later that night severe pains developed in the epigastrium, left shoulder and arm, intercostal muscles and left pectoralis muscle simulating angina pectoris. The leukocyte count and sedimentation rate were normal but a throat culture was later reported positive for pneumococcus type III. A course of penicillin was given intramuscularly, 25,000 units every four hours. After three days all muscular pain had disappeared, but the tonsils were still enlarged and contained purulent exudate. Aerosol penicillin was then given four times daily for three days, at which time the tonsils seemed to have shrunk to small masses of scar tissue. Two days after withdrawal of penicillin, all symptoms returned and the culture again showed pneumococcus type III. A final course of aerosol penicillin was given at home for seven days, with relief of all symptoms. Cultures were negative two days and one month after the end of treatment. The electrocardiogram, leukocyte count and sedimentation rate were normal. Because the tonsils do not look really healthy and are probably useless, tonsillectomy has been advised.

This involved case history is given rather fully to illustrate two points: First, allergic symptoms simulating viscerospasm and, later, angina pectoris were completely relieved by apparent cure of a type III pneumococcus infection of the tonsils. Second, aerosol penicillin succeeded in eliminating pneumococci from the tonsils, whereas large amounts of penicillin given intramuscularly failed to do so; moreover, the tonsils were smaller and more nearly normal after aerosol penicillin but remained large after parenteral therapy. Other patients with allergic disturbances due to chronic tonsillitis preferred to undergo tonsillectomy, preceded and followed by aerosol penicillin for three and four days, respectively. The course of treatment is shorter and chances of relapse much less when the tonsils are not retained. Surgical removal of foci of infection, such as the tonsils, is much less hazardous, and persistent infections are more frequently eliminated when penicillin treatment precedes and follows the operation.

Acute sinusitis. C. R., a woman aged 26, had her tonsils removed in infancy. At the age of 20 an attack of sinobronchitis persisted for several months. Roentgenograms showed a mild pneumonitis, which resolved during a month in Florida. Recently the patient had an acute attack of sinusitis involving both antrums and ethmoids; cultures showed nonhemolytic

streptococci, *Staphylococcus albus* and pneumococcus type VI. The infection was cured in two days with 200,000 units of penicillin. Findings were negative five months later.

It seems possible, in view of the previous history of sinobronchitis, that a recurrence of that condition was prevented by immediate treatment of the sinusitis at the onset of pain.

Chronic sinobronchitis. D. T., a woman aged 32, had lost many weeks of work for several years because of attacks of relapsing sinobronchitis lasting two or three weeks. In the latest episode, slight fever, pronounced fatigue and a productive cough were present. Sputum and throat cultures revealed only a nonhemolytic streptococcus; roentgenograms of the chest were negative for tuberculosis and bronchiectasis. Although the patient was unaware of allergic symptoms, skin tests revealed positive reactions to feathers and house dust. Fatigue and cough disappeared, with a high vitamin intake and three inhalations daily of 40,000 units of penicillin for five days, in combination with a penicillin nose spray of 250 units per cubic centimeter at night. The productive cough recurred in mild degree after the patient fluffed up some feather pillows, but it was again controlled almost completely with a few treatments of aerosol penicillin. As a prophylactic measure the patient continued taking a single daily inhalation for several weeks, since she was constantly exposed to upper respiratory infections. Immunization for the extrinsic allergies has been started.

The rapid action of aerosol penicillin in sinobronchitis is illustrated by this patient, who was able to return to work feeling well after five days' treatment, as contrasted with the protracted course of previous attacks.

At least 40 cases of sinusitis and sinobronchitis have been successfully treated with aerosol penicillin. Many cases have been complicated, as in the case of D. T., by extrinsic allergies which in themselves may produce respiratory symptoms. Zinsser,¹⁵ among others, has pointed out that when a chronic bacterial infection is eliminated the hyperergic state of the individual is diminished and food, pollen and other antigens cause few or no symptoms. In other words, the presence of a bacterial infection accentuates the allergic reactions to extraneous antigens.

ACUTE PHARYNGITIS ASSOCIATED WITH GASTRO-INTESTINAL SYMPTOMS

Patients are often seen with complaints localized in various portions of the body for which no definite etiology is easily discernible. Here the necessity of a thorough physical examination is more than ever of importance. Gastrointestinal upsets often fall into this category. Intrinsic bacterial allergy, heretofore a diagnosis which all too infrequently has entered into consideration, is receiving increasing recognition in the causation of obscure complaints referred to the gastrointestinal tract, the skin, the circulatory system and the respiratory apparatus. Recently it has been found that gastrointestinal complaints may be traced more or less directly to an infection of the upper respiratory tract.

Fourteen infants were seen primarily because of gastrointestinal disorders. These children had symptoms ranging from anorexia to vomiting, with or without loose stools loaded with mucus; in 2 cases there were green slimy stools containing undigested food and fats; persistent vomiting and constipation occurred in 2 cases, and in 2 other infants there were frequent very watery stools. Most of the babies were moderately sick and cried intermittently. Several had so-called colic, without other signs. Physical examination was generally negative except for moderate dehydration and, in all cases,

15. Zinsser, Hans. Resistance to Infectious Diseases, ed. 4, New York, Macmillan Company, 1931.

diffuse pharyngitis. Temperatures were never over 101 F. The white blood cell count varied from 12,000 leukocytes with 20 per cent polymorphonuclears to 25,000 leukocytes with 85 per cent polymorphonuclears. In 1 case with a hemolytic streptococcus throat infection the leukocyte count was 8,000, polymorphonuclears 4 per cent; after two treatments the polymorphonuclears increased to 40 per cent. The sedimentation rates ranged from 3 to 6 mm. per hour (Landau). The organisms identified by culture were hemolytic streptococcus, *Neisseria catarrhalis*, *Staphylococcus aureus* and *Staphylococcus albus*; in 1 case pneumococcus type XXXII was isolated.

Because of the pharyngitis all infants were treated with penicillin inhalations through the Barach-Eckman oxygen mask. After the first inhalation of 10,000 units the babies were more interested in eating, and the gastrointestinal symptoms were relieved. Second and third inhalations of 5,000 units were given to insure improvement or cure of vomiting and abnormal stools. Cultures of the throat were negative after therapy. More prolonged follow-up treatment was carried out when the infecting organism was a hemolytic streptococcus. However, in the normal infant very little penicillin treatment is usually required to eliminate symptoms arising from mild bacterial invasions of the upper respiratory tract.

A number of adults have been seen in whom treatment of a mild or chronic pharyngitis resulted in the relief of severe nausea and vomiting, acute gastric pain, migraine, hypertension and a Ménière-like syndrome. A report of these cases will be presented at a later date.

Pneumococcal pharyngitis and sinusitis associated with hyperemesis gravidarum. L. W., a woman aged 30, was depleted from almost continuous hyperemesis gravidarum when first seen in the fourth month of pregnancy. The only abnormal findings were a postnasal drip, mild pharyngitis and a leukocyte count of 13,000, with 76 per cent polymorphonuclears. Pneumococcus type XIII was found in throat cultures. The prolonged depletion was treated with parenteral injections of crude liver extract together with vitamins of the B complex and A, D, K and C. Because of the upper respiratory tract infection, 10,000 units of penicillin was added to the intramuscular injection of vitamins A and D in oil. After this treatment in the morning the patient ate a large meal at noon. In the evening she was troubled by anorexia and abdominal pain with emesis.

Since it appeared that bacterial allergy was a predominant factor, operating through the mechanism of intestinal migraine, ergotamine tartrate (Ergotrate) was given parenterally with temporary relief of symptoms. The patient was then given two aerosol penicillin treatments daily, and emesis stopped. The treatments were reduced to one daily, and on the following day vomiting again occurred in the evening. Complete relief of symptoms, without relapse, was finally obtained by four penicillin inhalations daily for five days. Whatever the actual mechanism of hyperemesis gravidarum in this case, it seems likely that there was an intrinsic allergy to pneumococcus type XIII. Complete remission of nausea and vomiting was attained with the control of pharyngitis and sinusitis.

INTRINSIC BRONCHIAL ASTHMA

The concept of intrinsic bronchial asthma, as distinguished from extrinsic asthma, has recently entered more frequently into consideration in the differential diagnosis of asthma.¹⁶ The prognosis of the disease is often very poor, and many patients suffering from the condition actually depend on epinephrine for their continued survival. The theory that a chronic bacterial infection in the upper respiratory tract is the causative

factor in intrinsic asthma is gaining acceptance. Some success has attended the treatment of bronchial asthma with nebulized solutions of sulfathiazole,¹⁷ often in combination with adrenergic bronchial dilators.

The earliest report on the application of penicillin in intrinsic bacterial asthma is that of Schonwald and Deppe,¹⁸ who used the drug with good results, although only very small and infrequent doses were given. Hampton and his co-workers¹⁹ studied 9 patients with asthma of many years' duration, of which group 8 patients reacted positively to extracts of common pollens, inhalants and foods. Elimination and injection therapy failed to alter the asthmatic state in any case. It was then assumed that the etiology was a primary bronchial infection (bacterial allergy). The patients received a course of at least 500,000 units of penicillin intramuscularly and later 500,000 units intratracheally by means of a pressure spray through a curved cannula extending to the base of the protruded tongue. There was slight clinical improvement in 4 cases, but not enough to indicate that penicillin offered any real advantages. It may be argued that with these methods of giving penicillin the drug did not reach the bacteria present in the respiratory tissues and excretions in sufficiently high concentrations to be effective. The droplets produced by the pressure spray were probably of too large a size to penetrate into the bronchioles.

Barach,¹ on the other hand, reported striking success in at least 2 cases of bronchial asthma, 1 of eight months' and 1 of twenty-five years' duration. Other patients, in whom emphysema, chronic bronchitis or both were also present, responded at least temporarily. It should be noted that these were all advanced cases, and aerosol penicillin was given arbitrarily for only ten days at most in an attempt to evaluate the technic. It is entirely possible that treatment over a longer period of time would cure more cases of severe bronchial asthma.

My experience has been more encouraging than that of Barach, probably because the cases treated had not progressed to the severe intractable stage with definite tissue change present in Barach's series. Aerosol penicillin has been very successful in 25 cases of bronchial asthma, a number of which also showed extrinsic allergies to foods, pollens or danders. While the disease may appear to be cured by a five day course of aerosol penicillin, it is advisable to continue therapy in diminishing amounts and then in single daily or weekly prophylactic doses for a number of weeks. Two cases are given here:

W. H., a boy aged 5 years, had relapsing episodes of sinusitis and bronchial asthma for three years. These attacks followed an acute upper respiratory infection with pyelonephritis and urinary frequency at the age of 2 years; leukocytosis was always present during these episodes. Throat cultures revealed hemolytic streptococcus (not typed) and pneumococcus type II. All skin tests for common irritants were negative. Penicillin was first used parenterally, 10,000 units every four hours for seven days, for one of these episodes. Temporary relief was followed promptly by a relapse. This was treated with a second course of parenteral penicillin, and relapse again occurred promptly. Finally aerosol penicillin was given, with complete relief of all symptoms, and no asthmatic symptoms have appeared in seven months. Several upper respiratory infections were aborted immediately by a few penicillin inhalations.

16. Cohen, M. B.: Bronchial Asthma: Classification Based on Etiological and Pathological Factors, *Ann. Int. Med.* 20: 590 (April) 1944.

M. G., a girl aged 10 years, had practically continuous episodes of sinobronchitis every winter to such an extent that she was never able to go to school. This condition had been present for eight years. She had never been very asthmatic, but the cough was very annoying and persistent. Ragweed hay fever occurred every fall. When first seen in September 1944 she had an upper respiratory infection involving both antrums and ethmoids, diffuse bronchitis and asthma. Many moist rales and rhonchi were heard in both lungs. There were no changes in breath sounds and no dullness. Roentgenograms revealed no signs of tuberculosis, pulmonary consolidation or bronchiectasis. She was found to be allergic to ragweed, house dust and feathers.

Initial treatment, 200,000 units of penicillin in doses of 20,000 units every four hours intramuscularly, was followed by a well defined general improvement, but a week later there was a relapse. The antrums were black to transillumination, and the condition of the lungs was about the same as when she was first seen. Penicillin therapy, 20,000 units four times a day intramuscularly, combined with a penicillin nose spray of 500 units per cubic centimeter, and sulfadiazine 0.5 Gm. daily, were given for seven days and then reduced to 20,000 units intramuscularly twice a day. It was two weeks before the antrums became clear to transillumination. The lung signs finally cleared up only when aerosol penicillin, 20,000 units four times a day, was given for five days. During all this time the child went to school every day for the first time in her life. She was treated from September to January more or less intensively and has felt well since treatment was instituted. From January to March she received one dose of aerosol penicillin once a week, 25,000 units, as a prophylactic measure. On March 8 she contracted what seemed to be a virus infection. The only bacteria detected on culture of the sputum and nasopharynx were nonhemolytic streptococci. Penicillin 20,000 units every four hours was administered for a week, and no sinusitis or bronchitis developed. Following this she had three days of aerosol penicillin, 25,000 units three times a day. In April she had a mild case of mumps. In May she had a slight cold with no sign of bronchial infection. At the present time she is in very good health and is getting ragweed and house dust immunizations twice weekly.

A pronounced side effect of combined aerosol penicillin and desensitization therapy for allergies, observed in this patient, will now be described.

SIDE EFFECTS OF AEROSOL PENICILLIN

A hitherto unreported side effect of penicillin therapy occurred in patient M. G. and in 1 other. If an aerosol penicillin treatment is given simultaneously or within a few hours of a pollen immunization or vaccine, severe allergic reactions develop; these are characterized by acute abdominal pain and urticaria, severe nervousness, restlessness and angioneurotic edema. Isonipicaine 50 mg., given either orally or parenterally, controlled the reaction within a few minutes. Aerosol penicillin alone never caused the reaction. The only other allergic reaction to penicillin was mild urticaria, which was relieved by Torantil (histaminase) within several hours. This occurred in 2 extrinsically allergic patients with sinusitis and is due to the pigment or other impurities present in commercial penicillin.

A few patients of Barach¹ complained of soreness under the sternum and an irritated throat after treatment with aerosol penicillin for a few days. Coughing sometimes was troublesome. Hampton¹⁹ was forced to discontinue the use of an intratracheal penicillin spray in 1 patient with intrinsic bacterial asthma because an attack was precipitated with each attempted treatment. The occasional coughing observed in my cases was not troublesome. It was a normal physiologic manifestation of the disease rather than a reaction to aerosol penicillin per se.

On several occasions patients mentioned the development of a sore throat sometime during the course of aerosol penicillin. The throats looked red and edematous. However, despite the continuation of aerosol penicillin, the throats became normal within the course of a few days. During the time this series of cases was treated, various unclassified virus diseases were prevalent in the community. It is felt that most patients complaining of sore throats had acquired an intercurrent virus infection or a highly resistant hemolytic staphylococcal infection.

The penicillin nose spray sometimes caused slight irritation, but in the same patients aerosol penicillin in much stronger concentration was nonirritating.

COMMENT

The average physician in general practice is not yet making full use of the potentialities of penicillin, probably because of the present inherent need of frequent and regular administration and its concomitant difficulties. In life endangering infections the drawbacks are minimized by hospitalization, although the inconvenience and dislike of frequent injections remain. The administration of penicillin by inhalation is suggested as a valuable substitute for the usual technic. It is an adaptable method, useful in the home by untrained persons and in the office. It can be utilized for continuous or intermittent administration of penicillin in severe as well as in less dangerous chronic infections, in which from three to five treatments during the day apparently are sufficient to effect removal of the infection. As demonstrated in the cases reported here, aerosol penicillin, as compared with parenteral penicillin, is usually more effective in the treatment of chronic and acute upper respiratory infections, with or without other systemic manifestations. The rapid clinical improvement in such stubborn conditions as intrinsic bacterial asthma is notable and encourages one to hope that at last a promising therapeutic weapon is available for that intractable condition. Likewise the amelioration and often the elimination of such manifestations as migraine, hypertension, chronic fatigue, gastrointestinal disturbances and fibromyositis, with the removal of chronic bacterial infections of the upper respiratory tract by aerosol penicillin, are startling and almost must be observed to be believed. The elimination of such bizarre concomitants of upper respiratory infection is difficult to explain unless the possibility of allergic reactions to a bacterial infection is entertained. Only a beginning at exploration of the widely varied ramifications of bacterial hypersensitivity has been made. It is entirely possible that penicillin may be a powerful and logical weapon in attacking this problem.

It must be emphasized that aerosol penicillin was repeatedly found to control infections of the upper respiratory tract which were not cured by parenteral penicillin or relapsed after its use. Plummer,²⁰ in a study of the treatment of hemolytic streptococcal pharyngitis and tonsillitis with parenteral penicillin, found that the organisms again could be cultured from the nasopharynx after cessation of treatment and relapse occurred within a few days. This occurred in 4 out of 9 patients treated for fewer than four days, in none treated for ten days. Such relapses did not occur in patients given aerosol penicillin. The use of intra-

20. Plummer, Norman; Duerschner, Dorothy R.; Warren, Harold D.; Rogliano, Francis T., and Sloan, Ruell A.: Penicillin Therapy in Hemolytic Streptococcal Pharyngitis and Tonsillitis, *J. A. M. A.* 127: 369 (Feb. 17) 1945.

tracheal sprays of penicillin, as reported by Hampton,¹⁹ was also far less effective than aerosol penicillin in bronchial asthma. From these and other data²¹ which have appeared since this report was submitted it is apparent that a strong case can be built up for the effectiveness of the local deposition of penicillin in the upper respiratory tract by inhalation of an aerosol.

Aerosol penicillin is not claimed to be a cure-all. It failed to influence the course of rheumatic fever, rheumatoid arthritis and other conditions in which penicillin has generally been ineffective. It has, however, surpassed other known technics in the persistent upper respiratory infections that cause so much chronic illness and disability and offer such a challenge to the physician. On the basis of its promising results, the method deserves a wider trial so that its value can be more accurately determined, especially when other methods are used to increase the individual's resistance to reinfection.

SUMMARY

The disabilities of more than 200 patients have been relieved or improved by adequate doses of aerosol penicillin, a technic whereby a highly concentrated solution of penicillin is inhaled as a mist. The cases fall into groups, the common denominator of which is a bacterial invasion of the respiratory tissues, including the paranasal sinuses, often associated with underlying disturbances. Although the disabilities are not all serious, they have produced prolonged periods of inactivity and loss of work. Many are of serious significance, as for example bacterial asthma, in which the mortality rate is high.

The conditions treated successfully include acute and relapsing pneumonitis due to various cocci; tonsillitis, sinusitis and sinobronchitis; pharyngitis with gastrointestinal manifestations, and intrinsic bacterial asthma. Several other manifestations of bacterial allergy (migraine, hypertension, eczema, rosacea, colitis, extreme fatigue and even mild psychoneurosis) associated with upper respiratory infections were treated with encouraging results.

The advantages of aerosol penicillin over parenteral administration, especially when respiratory invasions are under treatment, are many and include ease and adaptability of administration in the home or office through a mouthpiece or oxygen mask, relative cheapness, and local and systemic effectiveness. The inhalation of penicillin mist in concentrated doses introduces the therapeutic agent directly into the site of bacterial invasion and produces a very high local concentration. Moreover, a constant antibiotic blood level of penicillin may be produced by continuous penicillin inhalation through a positive pressure oxygen mask.

In addition to specific treatment of the bacterial invasion, management of the underlying factors is imperative. Parenteral crude liver extract and vitamin therapy are still important adjuncts to the specific treatment of most types of infection. Combined therapy has been effective and readily managed in general practice.

A previously unreported side effect of penicillin was observed in 2 allergic patients.

The aerosol penicillin technic is offered as a valuable new method for the general practitioner.

AND MILDRED W. BARNES
BOSTON

Several forms of penicillin have been identified in cultures of *Penicillium notatum*. Three of these, known as penicillin F, G and X in this country and as penicillin I, II and III respectively in Great Britain, have been isolated in crystalline form.¹ Other active substances have also been described which differ from these three in that they are probably proteins, non-diffusible, active only in the presence of glucose and are effective against gram negative as well as gram positive bacteria. The latter have been variously labeled notatin, penatin, penicillin B and "second factor" but are all closely related or identical.²

Commercial penicillins prepared from deep vat cultures consist almost entirely of penicillin G, but those prepared from shallow surface cultures in flasks may contain appreciable amounts of penicillin X varying up to 20 or 25 per cent.³

The only published paper in which more than mention is made of penicillin X is a brief one by workers of the Food and Drug Administration.⁴ That paper contains a summary of some of its properties and the results of a clinical trial in gonorrhea. When assayed by the cup-plate method, the potency of crystalline penicillin X is appropriately 900 Oxford units per milligram while crystalline penicillin G has a potency of 1,650 units per milligram. These workers found penicillin X to be more effective in vitro against a strain of type A Friedlander's bacillus and a strain of *Bacillus cereus*. They found no difference between penicillin X and commercial penicillin on four strains of *Staphylococcus aureus*, but in preliminary studies the former was found to be three to five times more effective than the latter in protecting mice against 10,000 lethal doses of

pneumococcus type I. In the treatment of gonorrhea they obtained bacteriologic cures in 64 of 68 cases (94 per cent) with a single intramuscular injection of 25,000 units of penicillin X but only 37 cures in 58 comparable cases (64 per cent) treated with a single intramuscular injection of 25,000 units of commercial penicillin. Moreover, 3 of the patients in whom they failed to obtain a cure with commercial penicillin were cured by a subsequent treatment with a single injection of 25,000 units of penicillin X. Consistently higher blood concentrations of penicillin X, as determined by a serial dilution technic in which *Bacillus subtilis* was used as the test organism, were maintained during the first two hours after an intra-

COMPARISON OF SENSITIVITY OF BACTERIAL STRAINS TO PENICILLIN X AND TO COMMERCIAL PENICILLIN

The tests for sensitivity were done in suitable mediums by the serial dilution method of Rammelkamp and Maxon,⁶ using 0.5 cc. amounts of both culture and penicillin solutions. Pathogenic strains, most of them from recent cases, were used. The staphylococci were all coagulase positive and included F. D. A. No. 209 P, one of those certified for penicillin standardization.¹ Various types were included among the group A streptococci, pneumococci and meningococci. Some of the strains were tested simultaneously with only one lot of each kind of penicillin, while others were tested at the same time with both lots of penicillin X and with

* Commercial lots are referred to as G. † Not included in the previous columns. Complete = no growth on subculture; Inhibition = no visible growth at 18 hours, growth on subculture. Not included in the table are tests with three strains of *Friedländer's bacillus* and one strain of *Hemophilus influenzae* which were equally resistant to the lots of X and G.

muscular injection, and the penicillin X was excreted into the urine somewhat more slowly than commercial penicillin.

Two preparations, one containing 65 and the other more than 90 per cent of penicillin X, were available for the studies to be reported in this paper.⁵ These studies fall into three categories: (1) Strains of bacteria obtained from clinical cases were tested simultaneously for their sensitivity to these two preparations and to various lots of commercial penicillin, (2) serum levels were compared after intramuscular injections in the same subjects and the levels obtained during therapy with different doses given by intermittent intramuscular injections were also compared, and (3) a preliminary clinical trial was made in a small number of cases mostly of pneumonias and gonococcal infections.

5. These were supplied by the Lederle Laboratories and Cutter Laboratories.

one or more lots of commercial penicillin. The results of all the comparisons are shown in the table.

It should be borne in mind that the standardizations of all penicillin preparations, according to international agreement,¹ is made with certified strains of *Staphylococcus aureus* which have the same sensitivity to penicillin F and G. Different strains of staphylococci, however, are known to vary considerably in their sensitivity to commercial penicillin⁷ and this was shown

elsewhere to be true for the strains used in this study.⁸ The present comparisons of the sensitivities of these strains of staphylococcus to penicillin X and G show that in the vast majorities of instances they were equally sensitive to X and G, to the two lots of X and to the various lots of G. The differences that were noted were mostly twofold and, interestingly enough, the strains showed greater sensitivity to the commercial preparations more often than to the lots of penicillin X. These findings tend to rule out differences in the standardization as a basis of the differences in the sensitivities noted with the other organisms.

All of the organisms other than the staphylococci were generally more sensitive to penicillin X than to penicillin G. Most of the group A streptococci, gonococci, and meningococci were from two to eight times more sensitive to penicillin X than to penicillin G. Most of the strains of *Streptococcus viridans* and of pneumococcus were twice as sensitive to X as to G. Three strains of Friedlander's bacillus and one of *Hemophilus influenzae* were equally resistant to the two. The significance of these comparisons is emphasized by the fact that when the sensitivity of these strains was tested with different lots of commercial penicillin the results usually agreed, and the differences observed with any two lots favored the one about as often as the other.

The two lots of penicillin X were essentially identical in their effects on the various strains of *Staphylococcus aureus*. Most of the other organisms showed either the same sensitivity to the two lots or a twofold difference, but they were generally more sensitive to lot C than to lot L, the latter containing only 65 per cent of penicillin X.

The standard strain of hemolytic streptococcus, No. 98, which was used for the determinations of serum levels, was included every time that other organisms were tested. The results of all the tests in which the sensitivity of this strain to different lots of penicillin was compared are also shown in the table. They did not differ essentially from the aggregate of the results obtained with the other strains of group A streptococci.

SERUM LEVELS

After Single Doses in the Same Subjects.—Ten convalescent patients were each given single intramuscular injections of 20,000 units of penicillin on two successive days. On the first day 5 of them received penicillin X and the others received commercial penicillin; on the second day each one received the alternate kind of penicillin. Blood was taken at hourly intervals for five hours after each dose, and the levels in the serum were determined by the serial dilution method of Rammelkamp.⁹ Human group O cells were used as an indicator. The same strain of hemolytic streptococcus, No. 98, was used throughout and the serum dilutions were added in 0.2 cc. amounts. The results are shown in chart 1 in terms of the reciprocal of the minimum serum dilution which sterilized 0.5 cc. of the culture. The corresponding concentrations of regular penicillin obtained in control tests with the same strain are also shown.

9 Rammelkamp, C. H.: A Method of Determining the Concentration of Penicillin in Body Fluids and Exudates, *Proc. Soc. Exper. Biol. & Med.* 51: 95 (Oct.) 1942.

There were appreciable differences in the maximum concentrations obtained and in the persistence of demonstrable amounts of penicillin activity in the serum in the different subjects with each of the preparations used. All received the same lot of commercial penicillin, while two lots of penicillin X were given—lot L to 6 subjects and lot C to 4. The levels obtained after penicillin X were consistently higher than they were in the same subjects after the same dose of regular penicillin. The differences were two to eight fold throughout the period corresponding to that during which regular penicillin was still demonstrable in the serum. In most instances also the penicillin X was found in concentrations of 0.03 unit per cubic centimeter or more for two hours longer than the commercial penicillin could be detected in the same subjects. Of the two preparations of penicillin X, the higher and better sustained levels were obtained with lot C than with lot L.

Levels During Intramuscular Therapy.—The levels of penicillin in the serum during the intervals between intramuscular doses in a number of patients under active treatment with penicillin X on four different

Chart 1.—Serum levels after single intramuscular injections of 20,000 units

dosage schedules are shown in chart 2. As might be expected, the larger doses gave rise to higher and better sustained levels than the smaller ones. A similar chart of serum concentrations obtained in patients under treatment with regular penicillin is given elsewhere¹⁰ and shows similar variations at somewhat lower levels. Comparisons of the average concentrations obtained on two similar dosage schedules of commercial penicillin and penicillin X are shown in chart 3. Values obtained in subjects with cardiac or renal insufficiency were excluded in the computation of these averages since they may be abnormally high.¹⁰ The average levels of penicillin activity in the serum, as measured by the use of streptococcus 98, were always at least twice as high during treatment with penicillin X as they were during treatment with the same doses of regular penicillin.

In chart 3 is also shown a comparison of the average serum levels obtained during the intervals between 10,000 unit doses of penicillin X and between 20,000 unit doses of regular penicillin, each given every three hours. Except at the one-half hour interval the average

10 Ory, E. M.; Meade, M.; Brown, B.; Wilcox, C., and Finland, M.: Penicillin Levels in Serum and in Some Body Fluids During Systemic and Local Therapy, *J. Lab & Clin. Med.*, to be published.

serum levels were slightly higher with the 10,000 unit doses of penicillin X than they were when twice that amount of regular penicillin was given.

CLINICAL OBSERVATIONS

A preliminary clinical trial of the use of penicillin X has been made on 75 patients. The less potent of the two preparations was used in almost all of these cases. Although the results of the studies on the sensitivity of various bacteria and the blood levels observed suggested that, as compared with regular penicillin, smaller doses spaced at longer intervals might give comparable results, no adequate attempt was made to confirm this possibility. The total doses used in most of the present cases, except in some of those of uncomplicated gonorrheal urethritis, were similar to the amounts generally employed with commercial penicillin. These doses were given chiefly for the purpose of obtaining data which could be compared with similar observations in other cases treated with regular penicillin.

Gonococcic Infections.—The difficulty of establishing a dose which would be universally effective in the treatment of gonorrhea has been pointed out recently.¹¹ In the present study 47 cases of uncomplicated acute gonorrheal urethritis were treated with total doses of 50,000 to 100,000 units of penicillin X given in two or three intramuscular injections at three hour intervals except for the 100,000 unit dose, which was given as

one after 75,000 units and the other after 50,000 units. In addition, 7 patients had clinical and bacteriologic cures for two or three weeks and subsequently returned with fresh infections after further admitted exposures to known sources of infection. Some of these reinfections responded with complete cure after smaller doses

Chart 3.—Comparison of average levels of penicillin activity in the serum of patients under treatment with various doses of commercial penicillin and penicillin X. Each point represents the average of at least ten observations in as many patients without cardiac or renal insufficiency.

Chart 2.—Serum levels obtained during the intervals between intramuscular injections in different patients under treatment with various doses of penicillin X.

five injections at two hour intervals. A total dose of 75,000 units was used on 23 patients and 50,000 or 60,000 units on 14. There were two definite failures,

11. Lapenta, R. G.; Weckstein, A. M., and Sarnoff, H.: The Inadequacy of a Standardized Dosage of Penicillin in the Treatment of Gonococcic Urethritis, *J. A. M. A.* 128: 168 (May 19) 1945. Seabough, D. R.: Penicillin in Treatment of Gonorrhea, *J. Missouri M. A.* 42: 272 (May) 1945.

than those used to treat the original infection. In 1 instance the organism isolated in the original infection was sulfonamide resistant while that cultured during the reinfection was highly susceptible.

The clinical impression gained from the close observation of these cases was that they responded somewhat more rapidly and more completely than cases treated with the usual 100,000 units of regular penicillin given in five injections at two hour intervals. This was generally evidenced by the rapid disappearance of symptoms and of discharge and the failure to find more than occasional leukocytes in prostatic secretions obtained on the day following treatment. This was in sharp contrast to the findings after the administration of large doses of oral preparations, when, in spite of negative bacteriologic findings in smears and cultures, the discharge and the symptoms often persisted longer than after the routine treatment with regular penicillin given intramuscularly.¹²

In cases of gonorrheal arthritis and epididymitis too the clinical response was quite rapid. Five patients with well established arthritis and purulent urethritis were treated with 20,000 units intramuscularly every three hours and single intra-articular doses of 5,000 to 15,000 units. All were entirely free from signs of infection within twenty-four hours, although stiffness and soreness in the joints persisted for several days during which the treatment was continued. In 2 additional patients there was joint tenderness and pain without swelling accompanying an acute urethritis, and a complete cure was effected in each instance by a total of 100,000 units given in four doses at three hour intervals. Two patients with severe epididymitis were completely relieved except for slight residual tender-

12. Finland, M.; Meads, M., and Ory, E. M.: Oral Penicillin, *J. A. M. A.*, to be published.

ness after the first day of treatment. One of them had urinary retention, probably resulting from acute prostatitis, and was relieved fairly promptly after the first injection was given.

Pneumonia.—Fourteen cases were treated with doses of 15,000 units of penicillin X every three hours. One patient, 72 years old, with diffuse bronchopneumonia of undetermined etiology complicating severe blood loss and congestive heart failure, died after two days of treatment. The others all had typical primary lobar pneumonia, previously untreated. A pneumococcus was identified from the sputum in 11 of these cases. They were all of moderate severity, but only 1 had a positive blood culture before treatment. They all responded promptly and were essentially afebrile and symptom free within twenty-four hours.

One additional case of a recurrent pneumococcus type 29 bacteremia in the terminal stages of obstructive jaundice from carcinoma of the ampulla of Vater was treated. The bacteremia cleared rapidly, but the same organism was found at autopsy in multiple milary abscesses of the lung mixed with Friedländer's and influenza bacilli.

Other Infections.—A case of staphylococcal bacteremia and pneumonia complicating carcinoma of the lung was treated for a few days with doses of 20,000 units every three hours. The bacteremia was rapidly cleared, but the pulmonary symptoms persisted. Three patients with severe and extensive cellulitis were treated with penicillin X. One of them had a severe aplastic type of anemia with agranulocytosis and died after two days of treatment. The other 2 showed rapid symptomatic improvement without further extension of the lesions, which then cleared over a period of a week. One received 15,000 units every three hours, and the other 20,000 units every four hours.

COMMENT

The methods used both in determining the sensitivity of bacteria and in estimating the serum concentrations are admittedly crude. Before the introduction of the international standards,¹³ the assay of the various commercial preparations of penicillin were likewise quite crude and involved appreciable errors.¹³ Possibly some of those errors and other discrepancies were due to variations in the proportions of the different forms of penicillin, as pointed out by others.¹⁴ It is most unlikely, however, that the consistent differences between the commercial preparations and the lots of penicillin X observed in the present studies could be explained on the basis of such errors. The similarity of the results obtained with the different lots of commercial penicillin serves to emphasize the superiority of the penicillin X.

The serum levels were determined with the use of a strain of hemolytic streptococcus which was more sensitive to penicillin X than to penicillin G. While this at first glance may seem to give only an illusion of higher levels with the preparation of X, it is nevertheless an expression of greater serum activity against the test strain. Since most of the other strains tested, exclusive of the staphylococci, showed a similarly greater *in vitro* sensitivity to penicillin X, a comparable superiority in therapeutic effect may be anticipated in infections with these strains.

The present results were obtained with commercial preparations which probably contained negligible amounts of penicillin X and were contrasted with lots containing different amounts of the latter form. Even the two lots of penicillin X showed appreciable differences in activity. Further studies are necessary to determine whether preparations made on a commercial scale from surface cultures and containing smaller amounts of penicillin X will show a proportionate superiority over the preparations which consist almost entirely of penicillin G.

It is obviously not possible to draw any definite conclusions from the results of the present preliminary clinical trial. The numbers of cases are too few and they were not adequately controlled to justify any deductions as to the therapeutic superiority of penicillin X. As far as one could judge from observing the patients clinically, the results of treatment with penicillin X were at least as good as those seen in similar cases treated with commercial lots. The gonococcal infections seemed to respond more rapidly and more completely. These results indicated that penicillin X, like regular penicillin, is nontoxic and highly effective in susceptible infections.

It still remains to be seen whether comparable clinical results can be achieved with significantly smaller doses or longer intervals by the use of penicillin X or with preparations containing an appreciable proportion of that form.

SUMMARY AND CONCLUSIONS

When tested simultaneously with preparations containing 65 per cent or more of penicillin X and with commercial lots which consist almost entirely of penicillin G, most strains of group A hemolytic streptococcus, gonococcus and meningococcus were from two to eight times more sensitive to penicillin X, most strains of pneumococcus and *Streptococcus viridans* were twice as sensitive to penicillin X and most of the staphylococci were equally sensitive to the two kinds of penicillin.

Levels of penicillin activity in the serum against a strain of hemolytic streptococcus were significantly higher and sustained longer after intramuscular injections of penicillin X than after injections of the same number of units of regular penicillin.

These findings suggest that comparable therapeutic results may be expected with the use of smaller doses or with the same doses given at longer intervals when penicillin X is used.

A preliminary clinical trial indicated that penicillin X is nontoxic and at least as effective as regular penicillin in the same doses in cases of pneumonia and probably more effective in gonococcal infections. Further clinical trials with the use of smaller doses and longer intervals are necessary in order to establish the therapeutic superiority of penicillin X.

Barber Surgeons.—Barber surgeons in the Middle Ages would notify the public that the time for bleeding had arrived by displaying a blood-soaked bandage at their doors, the origin of the familiar red-striped barber pole. The barber shops of Baghdad literally streamed with blood during the propitious periods for bloodletting. The practice of bloodletting was rigidly adhered to in the cloisters of the Church.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

LOW SODIUM CHLORIDE INTAKE IN THE TREATMENT OF INSOMNIA AND TENSION STATES

MICHAEL M. MILLER, M.D.

Associate Physician, St. Elizabeths Hospital
WASHINGTON, D. C.

Low sodium chloride dietary intake has been attempted in the treatment of epilepsy, migraine, Ménière's syndrome, hypertension, cardiac insufficiency and certain renal conditions with considerable success. In the treatment of epilepsy it has generally been regarded as efficacious in increasing the therapeutic effectiveness of bromides, while a number of authors have maintained that increased salt intake increases the frequency of convulsive seizures. In earlier dietetic literature, Friedenwald and Ruhräh,¹ for instance, in their discussion of the role of restricted salt intake, refer to past empirical clinical observations in which such a regimen was noted to have benefited certain "extremely nervous and irritable individuals."

Delaville and Tscherniakofsky² investigated the chloride content of the brains of a group of mental patients at autopsy and found increased chloride retention in most of these, thus suggesting the possibility of some relationship between certain mental disorders and chloride metabolism.

Von Noorden³ noted beneficial effects following the administration of a low salt diet to what he classed as "neurasthenic patients" but apparently believed that these effects were due to purely psychic-suggestive factors rather than to any specific effects associated with salt reduction. Nevertheless, it is of interest that von Noorden observed diminution in the skin reactivity to external stimuli in patients who had been deprived of sodium chloride in their diets. He attached particular significance to the resulting dehydration and increase of calcium ions in the tissues following sodium depletion. This view was supported by R. Schultz,⁴ who found that the cutaneous reactivity of the scalp was notably increased on a rich sodium chloride intake. In animal experiment Vogt⁵ clearly confirmed the earlier observations of Wertheimer and Abderhalden⁶ that acidifying diets tended to increase skin irritability in rabbits, while alkalinizing diets had the reverse effect. Further evidence accumulated revealed that the irritability of nerve tissue in vitro was increased by the excess of sodium ions and decreased by the addition of calcium ions. Clinically it was well known that a low sodium chloride intake altered the body fluids in the direction of alkalinity and

that excessive loss of chloride as a result of prolonged vomiting, for instance, would lead to alkalosis and tetany.

On the other hand, we are all quite familiar with the beneficial effects of a high sodium chloride intake in Addison's disease and of the interesting psychic effects of salt insufficiency in the addisonian patient. Further, that the addition of adequate amounts of sodium chloride to the diets of such patients frequently results in striking improvement in mental well-being. Recently Johnson⁶ reported observations on a group of persons suffering from mild degrees of hypotension, chronic exhaustion and lack of drive accompanied by a moderate degree of mental depression, in whom he found relatively low blood chloride levels not exceeding 450 mg. of chlorides per hundred cubic centimeters of whole blood; however, he did not report whether these patients had impaired chloride retention. He reported beneficial effects in all of these patients following the addition of 2 to 6 Gm. of salt to their daily diet, noting gratifying symptomatic relief after four to five days, with a return to the former symptoms following the removal of the added salt.

On the basis of these observations concerning the role which sodium chloride appears to play in certain mental disorders, it seemed appropriate to attempt to observe the effects of salt reduction in patients suffering from severe tension and insomnia states.

SUBJECTS AND PROCEDURE

Observations were conducted on a group of 20 patients with pronounced insomnia, nervous tension, anxiety and increased emotional lability. They ranged in age from 20 to 53 years. Sixteen were men and 4 women. Six were postmorphine addicts,⁷ 6 were merchant seamen⁸ suffering from so-called convoy fatigue with insomnia and anxiety, and 8 were patients under treatment at the New York State Psychiatric Institute. Of this latter group of 8 cases 4 had been diagnosed as psychoneurotic, 4 as early cases of schizophrenia. All patients were observed for a minimum period of one week prior to being placed on a restricted salt regimen, during which time their behavior in the ward and their nocturnal sleep were observed. In each case the blood and urinary chlorides were determined prior to treatment, and in 9 subjects the urinary chloride excretion was carefully checked at intervals throughout the treatment period. The blood chloride controls were not continued, as they were not considered a reliable indicator of the body chloride level, since low tissue levels have been observed despite higher blood values.⁹ Diurnal electroencephalographic tracings were done on the control group of 8 patients before, during and after the dietary regimen. Nocturnal electroencephalographic records, unfortunately, could not be obtained at the time. The method of salt reduction consisted in utilizing a low salt, neutral ash diet which contained considerable leafy vegetables and potatoes, to which approximately 0.5 to 2 Gm. of sodium chloride was added daily. This high potassium-containing diet furthered the chloride excretion. Five subjects in the series were given severely restricted diets containing not over 0.5 Gm. of salt per

Dr. Bernard L. Pacella made the electroencephalographic recordings and interpretations. Dr. Irville H. Mackinnon selected the patients.

Read at the centennial meeting of the American Psychiatric Association and before the Section of Neurology and Psychiatry, District of Columbia Medical Society, Washington, D. C., on Dec. 7, 1944.

Dr. Nolan D. C. Lewis, director of the New York State Psychiatric Institute, and Dr. Frank M. Faget, chief medical officer of the Ellis Island Marine Hospital, U. S. Public Health Service, made this investigation possible.

Dr. Ernst P. Pick of Columbia University guided in the preparation of some of the material of the manuscript and conducted parallel animal experiments in order to shed some light on the physiologic mechanisms involved in sodium chloride depletion.

day for a limited period. During the period of observation no other treatment was administered, and sedative medication was withheld except when absolutely essential. The subjects were permitted to maintain the same daily routine to which they were previously accustomed. After completion of the preliminary clinical and laboratory control observations the subjects were placed on a low salt regimen for periods varying from twenty-one to forty-two days. During this time the length and character of sleep, blood pressure, weight and urine output were recorded. Fasting blood sugar was controlled in 3 patients. For control purposes the aforementioned 9 subjects were given 9 Gm. of sodium chloride daily in the form of enteric coated tablets and were kept on the salt restricted diet for an additional two to three weeks. Subsequent to this the regular hospital diet was resumed and the sodium chloride tablets were discontinued. The aim of the control procedure was to add an amount of salt which would be consistent with an approximately normal intake. Since most authorities agreed that the average daily intake of salt may vary from 10 to 30 Gm., and that 3 to 5 Gm. is usually sufficient to maintain an adequate body chloride level, it was decided to add 9 Gm. daily to the experimental diet for control purposes. Actually under normal conditions not over 5 Gm. is assimilated daily by the body, the surplus being excreted via the kidneys, the sweat glands and the gastrointestinal tract.

The following criteria regarding the character of sleep served as guides in observing these patients: The onset, duration, continuity and regularity of sleep, motility during sleep, ability to fall asleep after being awakened, diurnal drowsiness and afternoon sleep, and rest obtained from sleep as well as dream phenomena were noted. In addition, the general psychiatric picture including mood, concentrating ability and activity drive of the patients were observed.

OBSERVATIONS

During the initial period of the diet the usual diuretic effects were observed and the loss of body fluids appeared to parallel closely the chloride excretion. In no instance was dehydration or weight loss important. After four to seven days on the diet the majority of the patients began to exhibit a gradual decline in nervous tension, irritability, activity drive and restlessness, accompanied by increased ability to fall asleep and a general improve-

Fig 1 (case 1)—Comparison of sleep and urine chloride excretion. Heavy line, hours of sleep, light line, grams of urine chloride.

ment in the character of sleep. It will be noted (figs. 1, 2 and 3) that the urinary chloride excretion remained consistently lower than prior to treatment. Physical signs such as diminution of reflex activity, reduced skin reactivity and diminished finger tremor were noted. There were consistent gradual declines in blood pressure varying from 10 to 40 mm. systolic and moderate decline in pulse rate, usually falling to low normal levels, ranging from 60 to 72. It was further observed that when

a definite decline in urinary chloride excretion was achieved the subjects fatigued more readily, tending to retire at an earlier hour, usually falling asleep within ten to fifteen minutes, and sleeping soundly until awakened at 6 a. m. The maximum amount of sleep permitted was eight hours. As far as could be observed by the attendants, motility during sleep appeared considerably reduced. It was consistently noted that when the sub-

Fig 2 (case 2)—Comparison of sleep and urine chloride excretion. Heavy line, grams of urine chloride. Light line, hours of sleep.

jects were awakened by a desire to urinate during the phase of increased diuresis they readily fell asleep again, whereas formerly they had experienced considerable difficulty in regaining sleep after awakening. After two to three weeks on the diet a notable decline or absence of dream phenomena was consistently observed among the subjects. In several patients there was not only a substantial lengthening of the duration of sleep but also a tendency toward drowsiness during the afternoon hours accompanied by signs of moderate muscular fatigue. Some of the subjects formed the regular habit of taking afternoon catnaps, to which they were not previously accustomed.

In general, psychomotor activity was reduced and the patients appeared more relaxed and in some instances even phlegmatic. There was a reduction in nocturnal emissions and of sex dreams in some cases. In general, a distinct decline in the intensity of emotional response became discernible, and the subjects no longer seemed unduly excited by incidents which formerly evoked manifest signs of emotional disturbance. In some of the patients on the severely salt restricted regimen the effect bordered on apathy, patients generally giving an impression of increased calm and stability. Following the onset of more normal sleep habits, general improvement in mood was observed. There was improved ability to concentrate, as revealed by the manner in which patients performed various tasks. One subject who had been unusually tense observed that he was able to concentrate satisfactorily on reading material for the first time in the twenty-nine months he had been at the institution. Three of the subjects suffering from frequent severe headaches which had contributed appreciably to their emotional state and insomnia obtained partial or complete relief after two or three weeks on the diet. One subject suffered from an intermittent peripheral vascular disorder diagnosed as Raynaud's disease, characterized by periodic episodes of numbness, palm and blanching of the extremities, hands and feet, accompanied by considerably increased psychic tension and anxiety. He exhibited pupil dilatation and considerable perspiration, particularly from the volar surfaces of the hands and feet. After approximately three weeks on the diet this subject showed considerable relief from his vascular disorder, rested better and made a general impression of increased stability, calm and

diminished anxiety and tension. Of the patients treated, 3 failed to respond satisfactorily and the diet was discontinued. Two of these were patients with a fairly high degree of habituation and physical dependence on barbiturates, and 1 of the latter was a schizophrenic with accentuated delusional activity.

The fasting blood sugar levels on 3 controlled subjects showed a considerable decline, varying from 10 to 40 mg. in the third week. The significant fact was that the blood sugar of each of these patients, though maintained on an identical fairly constant diet, reached almost equal levels of 80 to 81 mg., although the original blood sugar showed a 40 mg. variation. This blood sugar alteration was paralleled by simultaneous reductions in blood pressure and pulse rate. Of 13 patients given the sodium chloride placebos for control purposes, 10 developed sleep disturbances after seven to ten days. (fig. 3).

No abnormal electroencephalographic activity was produced as a result of the diet. During the course of clinical improvement there was generally an increase in the alpha index, with some diminution in the incidence and regularity of alpha activity during periods of increased tension (fig. 4).

Fig. 3 (M. S., Psychiatric Institute).—Note that on the eighteenth day 2 Gm. of sodium chloride was added to the salt restricted regimen owing to the fact that the urine chloride excretion had fallen to less than 4 Gm. in twenty-four hours, thus causing an upward deviation of chloride excretion curve. This chart illustrates the effect of giving sodium chloride disguised as placebos during the control phase. The arrow indicates the point when the control salt was given. Note the reduction and irregularities in the pattern of sleep after nine days on the salt control. See figure 4 for electroencephalographic alterations on this patient. The patient was permitted a considerable increase in meat and milk intake during the control phase, thus causing a fairly considerable increase in the sodium chloride excretion.

Some of the representative case histories follow:

REPORT OF CASES

CASE 1.—C. T., a white woman aged 24, admitted to the Psychiatric Institute on Feb. 29, 1944, exhibited noticeable anxiety, seclusiveness and preoccupation over certain obsessive ideas accompanied by a considerable dread of falling asleep for the past several months. It was observed that she showed little social drive and obvious feelings of insecurity in the presence of others. She would manifest periodic attacks of forced breathing, staring into space motionless with intermittent crying spells, which would stop abruptly. She had frequent fearful dreams, usually associated with delusions of being attacked violently with resulting physical harm. The low salt diet was instituted, and all sedative medication which she had been receiving for five weeks at the institute with unsatisfactory therapeutic results and for some time previous to admission was discontinued.

During the initial period on the diet, the patient showed considerable diurnal tension and sleep irregularity. A notable improvement occurred on the thirteenth day, when she appeared considerably relaxed, her anxiety greatly reduced, and she slept for eight and one-half hours. From this time on she showed continual improvement with much improvement of her mental state paralleling her improved sleep, as can be noted from figure 1.

More recent data revealed that this improvement persisted; the patient showed weight increase, appeared calmer and was able to participate better in various activities such as bridge and ping-pong, which she had refused previously. Improvement in mood was striking, following her improvement in sleep. She discussed her conflicts without producing the sharp emotional discharge which was manifested previously. She had no fearful dreams during the period of improved rest. Of further interest is the fact that when later given enteric coated salt tablets (9 Gm. daily) she showed a rather rapid return toward her former mental state and sleep disturbance.

CASE 2.—I. Z., a white man aged 43, admitted to Ellis Island Marine Hospital on Jan. 27, 1944, complained of a high degree of emotional irritability, restlessness and insomnia, accompanied by symptoms of dizziness of a periodic paroxysmal character, palpitation of the heart and sweating. The patient gave a history of a long persisting state of increased tension and insomnia, which followed industrial chronic mercury poisoning incurred five years before. For several years he received considerable amounts of barbiturates and later bromides, building up a considerable dependence on these drugs, but stated that he obtained little subjective relief from them. He stated that he had had no such medication in the last year.

The patient was placed in an observation ward for five days. It was observed that he was decidedly restless; that he slept only one or two hours per night, usually in brief catnaps with

wakeful intervals. He showed signs of subjective and objective fatigue. His weight was 170 pounds (77 Kg.), his height 5 feet 8 inches (173 cm.).

On initial physical examination he appeared well nourished. His blood pressure was 130/70. There were hyperactive reflexes and fine finger tremor. The pupils were somewhat dilated and reacted promptly to light. Dermographism was increased. Most upper teeth were absent; there was some pyorrhea of the lower, with a gray zone on the gingival margin.

On Jan. 31, 1944 a salt free diet was instituted. The patient showed the usual increased diuresis and on the third day noted that his sweating was considerably reduced. It was noteworthy that after several days the patient's water intake diminished materially although he was permitted all the fluids he desired.

As seen in figure 2, following the first week on the salt restricted regimen the patient began to rest better; however, there was no especial improvement in sleep until the fifteenth night, when he slept seven and one-half hours and fell asleep without difficulty. He began to fatigue more easily and after three weeks complained of slight aching of the calves. From then on he averaged from seven to eight hours of restful sleep per night until the thirty-eighth day (fig. 2), when he showed signs of increased irritability, tension, abdominal cramps, anorexia, tremor (finger), hyperactive reflexes, restlessness and sleep disturbance. His salt excretion (urinary) had fallen to 2.94 Gm. in twenty-four hours, and his urine was consistently alkaline. This drop of from 14 to less than 3 Gm. of urinary chloride excretion per day occurred after thirty-six days on the salt restricted diet. It was concluded that the patient was alkalotic and sodium chloride was administered (6 Gm. daily), following which there was a fairly rapid improvement and relief from symptoms.

The patient exhibited a drop in urinary chloride excretion of from 14 to less than 3 Gm. in twenty-four hours. During this time he exhibited increased diuresis, losing approximately 13 pounds (6 Kg.). His blood pressure went from 130/70 to 90/58, the blood pressure beginning to show clearcut decline after two weeks on the diet and then remaining consistently low. During the time that the urinary excretion of chloride remained above

3 Gm. in twenty-four hours the patient felt relieved of his tension and showed a decided improvement in sleep. No ill effects were noted until urinary excretion fell below 3 Gm. a day.

COMMENT

With reference to the findings, it is noteworthy that subjects with insomnia show a lower percentage of records with high alpha indexes than the general population.

In evaluating the results of the moderately restricted diet containing 2 Gm. of sodium chloride daily as compared to the rigidly enforced regimen permitting not over 0.5 Gm. per day, it was our impression that the former procedure was distinctly more beneficial and better tolerated by the patients. Observations by Kirsner and his co-workers¹¹ and other investigators show that the nonprotein nitrogen is not elevated appreciably by gradual dechloruration. McCance and Widdowson¹² observed severe nitrogen retention following rapidly induced experimental hypochloremia and alkalosis produced by diet and sweating. Patients should be watched for signs of hypochloremia, such as excessive muscular weakness, listlessness, fatigue, anorexia, intestinal cramps and gastric upset, associated with nausea, apathy, dizziness, tachycardia, cardiac arrhythmia, muscular twitching and achlorhydria.

Although diuresis was particularly increased during the initial period of treatment, no persisting urinary frequency or bladder discomfort was noted. Diabetes mellitus, severe renal dysfunction and advanced coronary disease were considered as contraindications to this form of treatment. A word of caution might be added concerning a too rigid salt curtailment in hot weather, since the loss through perspiration is considerable and salt lost in this manner cannot be regained by the body. While under treatment no heat therapy should be administered and excessive physical exertion should be forbidden.

No harmful effects were observed in those patients receiving the moderately restricted diet. Attempts were made to stabilize the daily urinary chloride excretion at a level of 4 to 6 Gm. in twenty-four hours, and sufficient salt was added in order to achieve this level of excretion. Thus frequent checks of the urine chloride excretion and acidity are of considerable control value. A simple and sufficiently accurate method of controlling the urinary salt excretion is provided for in the test devised by Fantus,¹³ which gives a definite quantitative result.¹⁴ These determinations can best indicate

the basic sodium chloride requirement of the patient. Thus complications can be avoided which might result from too prolonged salt restriction with the subsequent alterations in acid-base equilibrium and fluid balance. On the moderately restricted regimen a satisfactory stabilization level of chloride excretion is usually attained after seven to fifteen days and the sodium chloride intake can be increased to 3 to 4 Gm. daily. Patients who on initial examination showed impaired chloride retention, particularly when this is accompanied by clinical signs of chronic exhaustion, hypotension and muscular weakness, should not be subjected to this treatment.

B.M.

M.S.

Fig. 4.—A, pretreatment; B, low sodium chloride intake; C, sodium chloride control.

There is evidence that a definite shift of acid-base equilibrium toward alkalinity leads not only to the symptoms of physical distress accompanying hypochloremic alkalosis but also to a state of increased irritability and sleep disturbance (fig. 2). This reversal phenomenon appears to be based on the state of acid-base balance; for instance, of interest is the fact that patients with circulatory acidosis, as in cardiac insufficiency, tolerate drastic chloride restriction quite well for considerable periods of time in contrast to patients without circulatory insufficiency. In the nonacidotic patient it is neither necessary nor wise to enforce a too rigid curtailment of salt. Reduction of the urinary chloride excretion to a level of 3 Gm. or less per day is distinctly undesirable and may even be harmful. Drastic sodium chloride restriction, according to Cohn

14. Ten drops of a twenty-four hour urine specimen are put in a test tube with a dropper pipet followed by one drop of 20 per cent potassium chromate. Silver nitrate (29 per cent) is then added drop by drop and shaken until the color changes sharply from canary yellow to orange brown. The number of drops of silver nitrate used gives the number of grams of sodium chloride per liter of urine and is calculated on the basis of the total urine output for twenty-four hours.

and Soskin,¹⁵ tends to lower the oxidative processes in the tissues and thereby results in the accumulation of lactic acid and other fatigue products in the blood and muscles. This may be manifested in salt restricted patients by such symptomatic complaints as muscular aches and fatigue. These authors have further pointed to the important role of chloride anions and sodium cations in the transfer of oxygen from the blood to the tissues and in the removal of carbon dioxide. They have clearly demonstrated by means of both *in vivo* and *in vitro* experiments that the total oxygen consumption of dogs that have been depleted of sodium chloride is abnormally low and is permanently restored to the normal value by administering sufficient amounts of sodium chloride.

For some time there has been considerable controversy concerning the relative effects of chloride depletion versus bromide action. The consensus at present appears to be that bromides exert a direct depressant effect on the nerve cells but that this action is enhanced by the fact that bromides are readily able to displace chlorides from the body tissues, thus increasing the capacity of the tissues for the assimilation of bromides. The question of how much of this depressant action is due to bromide effect and to what extent this effect might be due to the secondary loss of chlorides has remained still unanswered but is an interesting consideration in view of our observations.

In favor of the latter possibility, it is pointed out that bromide action is more effective when the chloride in the diet is reduced. Further, the addition of chloride to the diet usually relieves symptoms of bromism and restores epileptic seizures which have disappeared following bromide medication. Jacques Loeb¹⁶ found that certain fish are depressed by bromide solution but remain normal if chloride is added. It was felt that further clinical observation on the effects of dietary salt loss might throw more light on the role of chloride loss in the aforementioned mechanism.

From these observations it appears that chloride depletion results in a depression of central as well as peripheral nervous reactivity and that this effect can be demonstrated by means of animal experiments. Animal studies that Dr. E. P. Pick and I¹⁷ conducted showed a pronounced reduction in the brain electrical activity following sodium chloride depletion.

It is of additional interest that during the periods of clinical improvement the reduction in nervous tension was accompanied by certain indications of reduced adrenomedullary activity, as evidenced by declines in blood sugar, blood pressure and pulse rate. Whether these alterations are due primarily to central or to peripheral factors or both is not yet clear. Further, the question as to whether the loss of sodium chloride or the increased accumulation of fatigue products acts on the central sleep centers also cannot be answered at this time.

The value of prolonged administration of sleep inducing drugs in psychiatric therapy can certainly be regarded as a sort of necessary evil. An important drawback in the use of such medication is that natural physiologic sleep is not usually produced and that patients frequently feel poorly rested in spite of the induced sleep. The administration frequently of hypnotic drugs to relieve tension and anxiety states does not always give satisfactory results. For instance, increased central excitability can often be observed following the cessation of barbiturate action. Furthermore, the true mental picture may be obscured or altered by such medication. Obviously there is the necessity of rehabilitating patients to a more normal physiologic sleep routine, which substantially aids in the development of a more favorable alteration in mood and a reduction in tension. In many instances this objective is not satisfactorily achieved by means of sedative medication.

The advantages of employing a drug free method of caring for such states is quite obvious. Undesirable complications such as the development of drug tolerance, habituation and physical dependency and the harmful physical effects of prolonged medication need no reiteration here.

It is felt that further study along these lines is indicated and that considerable additional data could be secured by means of electrical skin resistance studies, nocturnal electroencephalograms and further blood sugar controls.

The possibility that salt reduction may potentiate the sedative action of certain drugs is being explored.

CONCLUSIONS

Twenty patients suffering from insomnia and tension states were treated by means of a salt restricted dietary regimen with the following results:

1. Pronounced or moderate relief from tension and insomnia were observed in all but 3 of the cases.
2. Controls on 13 patients revealed that 10 patients suffered relapses following the addition of salt to the diet.
3. Improvement was noted generally in the duration and regularity of sleep, with a concurrent reduction in lability and intensity of emotional response on the lower salt intake.
4. No abnormal electroencephalographic alterations followed sodium chloride reduction, and better alpha indexes were observed in those patients exhibiting clinical improvement.
5. No untoward effects were observed in patients receiving moderately restricted salt diets.
6. Improved sleep and reduction in tension was usually accompanied by lowered blood pressure, pulse rate and additional evidence of reduced sympathetic tone.
7. The actual psychiatric condition of the patients is not materially altered, except as it might be benefited by reduction in tension and improved rest.
8. The application of low sodium chloride diets as described is suggested as an important adjunct to psychotherapeutic measures in the treatment of insomnia and tension states.

TREATMENT OF ACUTE THYROIDITIS
WITH THIOURACIL

PRELIMINARY REPORT

BRIEN T. KING, M.D.

AND

LEO J. ROSELLINI, M.D.
SEATTLE

Prior to Sept. 18, 1944 the treatment of acute thyroiditis had in our experience been unsatisfactory. On that date a young woman with the outward appearance of good health, the wife of a physician, presented herself at our office with the following history: She had enjoyed good health all her life except for diseases of childhood. She had had no recent infection. One week before, her thyroid gland had become swollen and quite sensitive to pressure. The gland was somewhat painful on swallowing. Generally she had not felt well, was more nervous, was rather irritable and had a tendency to increased perspiration. She had been more conscious of her heart action and had a moderate elevation of temperature. She thus complained of the general symptoms of a mild infectious process.

Physical examination revealed that the patient was apparently of good nutrition and good color. The only important findings were an acutely tender and swollen thyroid gland, a temperature of 99.6 F. and a white blood cell count of 9,600 per cubic millimeter with polymorphonuclears 64 per cent. Her heart, lungs and blood pressure were essentially normal. A diagnosis of acute thyroiditis was made.

It was explained to her that we knew of no satisfactory treatment for acute thyroiditis, that the disease was somewhat self limited and usually ran its course in a period of from six weeks to six months and that x-ray therapy usually shortened the course of the disease but that in our experience the patients on whom it was not used on the average wound up with a more normally functioning thyroid gland than did those on whom it was applied. We suggested that if she was willing to be the "guinea pig" we would like to try thiouracil as a therapeutic measure. She willingly assented and was told to take 0.2 Gm. of the drug three times daily. She was instructed as to its dangers and requested to have a white blood cell count every two or three days. In one week she returned stating that she was completely well and free from symptoms. That report was verified with one exception. This was that the gland had not changed in size and was still harder than a normal thyroid gland. The tenderness of the gland had disappeared, her temperature was normal and the white blood cell count was normal. The dose of the drug was reduced to 0.2 Gm. once daily and continued for two weeks. Since then she has been kept under observation for four months. The gland has returned to normal size and consistency and also to normal function.

Thinking that the result obtained might be an accident or the result of a mild type of thyroiditis, we waited patiently but hopefully for an opportunity to try the treatment on other patients with acute thyroiditis.

Before going into further detail in the report of a group of such cases, it seems fitting to discuss general considerations, previous treatment and the results obtained.

We have used iodine, rest, hot applications, ice bags and x-ray therapy. When the sulfonamide drugs came out, with the thought that acute thyroiditis was possibly an infectious process, we tried them. As well as we could determine, no benefit to the patients resulted from their use. One woman with unusually severe thyroiditis referred to us in the third week of the disease had had a temperature rise as high as 105 F. She was placed on sulfathiazole and as far as we could determine received no benefit. We have treated several other rather severe cases of thyroiditis with the sulfonamide drugs and none seemed to be benefited. We have not used penicillin, as until recently it was not available. Therefore we do not know whether it would be beneficial or otherwise.

Prior to September 1944, as previously stated, the only therapeutic agent that had definitely seemed to shorten the course of the disease was x-rays. Their use was followed in a discouraging percentage of cases by varying degrees of hypothyroidism or myxedema. No constant dosage of x-ray therapy was used, but in all cases so treated the dosage was much less than would have been indicated in cancer of the thyroid gland.

During the past twenty years, for varying reasons, we have operated on a few patients with acute thyroiditis. Cultures, both aerobic and anaerobic, of the tissues removed were made in most of the operative cases. All were negative for growth. We have not had available facilities for virus cultures and therefore do not know whether they might be positive.

We believe that biopsy cultures for the determination of the presence or absence of virus infections in a limited number of early cases of acute thyroiditis, performed by those qualified and equipped to make such studies, to be not only justifiable but a desirable experiment. In the light of our experience in the treatment of this disease by thiouracil, the proved presence of virus infection would open a field of very interesting research in the therapy of virus disease in general.

Histologically, the removed tissues showed varying degrees of inflammatory changes and evidences of destruction of the epithelial elements of the glands. Strangely, in a considerable percentage of all cases of acute thyroiditis that we have examined there was been a history of recent mouth or pharyngeal infection.

In the cases in which operation was performed, sufficient time had elapsed between the onset of the disease and the date of operation possibly to account for the absence of bacteria in the removed tissues. However, we have no evidence that they had been present at any time.

Included in this report are 7 cases of acute thyroiditis, 3 cases of migratory thyroiditis and 1 of struma lymphomatosa (Hashimoto's struma). No patients with suppurative thyroiditis, Riedel's struma or chronic inflammatory changes associated with the degenerative changes of long-standing colloid and adenomatous goiter are included, nor are the cases of toxic diffuse goiter with lymphoid hyperplasia included. Patients with "migratory thyroiditis" described by one of us¹ are included.

Material for this article was drawn from the thyroid service at King County Hospital and from private practice.

Dr. H. Sidney Newcomer and Mr. P. A. Freeman of E. R. Squibb & Sons and Dr. George R. Hazel and Mr. L. C. Beck of Abbott Laboratories supplied the thiouracil.

1. King, B. T.: Thyroiditis, *West. J. Surg.* 41: 391 (July) 1933.

The diagnosis of acute thyroiditis is purely a clinical one. Microscopic examination of the gland is rarely possible and the taking of a biopsy specimen entirely unwarranted from a purely diagnostic standpoint. The disease is usually of more or less sudden onset, occurring in a previously normal gland or one slightly enlarged. We have not seen it develop in a previously existing goiter of any type. It is associated with slight to moderate enlargement of the thyroid gland, which is usually quite tender and frequently painful. The gland is quite hard. Patients often complain of some pain on swallowing or turning the head. They discover that the gland is tender to touch. They complain of fatigue, lassitude, weakness, nervousness and not feeling well. The temperature usually ranges from 99 to 102 F. A few have been afebrile. The highest temperature associated with any patient we have examined was 105 F. Incidentally, this patient had the largest gland we have seen associated with the disease. The basal metabolic rate is usually slightly above normal. In none has it been above a plus 20 per cent. In many particulars the disease resembles mild hyperthyroidism and can easily be mistaken for it except for tenderness and fever. It also does not respond to Lugol's solution. Frequently there is an elevation of the number of white blood cells.

Migratory thyroiditis is no doubt the same disease as the more commonly described type of acute thyroiditis and was so designated because it varies from the usual type in one particular: It usually begins in the upper pole of one or the other lateral lobes and progresses by extension to involve the entire gland. The time required for involvement of the whole gland varies from a few days to three weeks. Prior to the present reported group of cases we had seen no case of migratory thyroiditis in which the entire gland did not become involved in the swelling and tenderness.

In 3 of the 11 cases here reported there was migratory thyroiditis, in 1 of which at the time of examination it had extended so that the entire gland was involved. In the second case of this classification the drug was not tolerated; it had to be discontinued, and the process went on to include all of the gland. Case 9 in the series was of one week's duration at the time of examination. The right lobe was more than twice the size of a normal lobe, quite apparent to casual inspection and very tender and hard. The isthmus and left lobe were normal in size and consistency and not tender. The patient had an elevation of temperature and white blood cell count plus a moderate elevation of the basal metabolism and the usual general symptoms of the disease. She was promptly given thiouracil in the usual dosage. In one week she was symptom free except for the enlarged and hard right lobe. The process had not extended to the isthmus or the left lobe. The involved lobe has now returned to a normal state in a period of four weeks. This is the only time we have seen acute thyroiditis limited to one lobe and believe it is due to the action of thiouracil.

Of the 11 cases so diagnosed and treated with thiouracil, 8 may be placed in one category. In all 8 patients the process was three weeks or less in duration. All were symptom free in one week, and in all the enlargement has completely disappeared. In case 9, 1 of those with migratory thyroiditis, the drug was not tolerated and it had to be discontinued. Little benefit resulted.

Of the remaining 3 patients who did not respond to the drug, 1 had previously been given a diagnosis of toxic goiter and had taken 10 drops of Lugol's solution

three times daily for three months. The history seemed to us to warrant a diagnosis of acute thyroiditis. She has made little improvement on thiouracil and we now know that our diagnosis was incorrect.

Patient 10 had been treated five months previously with x-rays, receiving a total of 1,800 roentgens, and was past the active inflammatory stage. She still has a rather large hard gland that is quite fixed. Three weeks' treatment with thiouracil has caused no appreciable change in the condition, possibly because of the changes induced by x-rays and possibly because the acute stage of the disease is past and the structural changes in the gland are now irreversible.

Patient 11 gave a history of having been previously given a diagnosis of toxic goiter and treated with Lugol's solution 10 drops three times daily for three months. There had been no improvement in the symptoms when we examined her and the history seemed to warrant a diagnosis of acute thyroiditis. She was put on 0.2 Gm. of thiouracil twice a day for a week and then once daily for two weeks. She received no benefits and there was no change in the size of the gland. Subsequently she was operated on and microscopically proved to have Hashimoto's struma. Microscopic sections showed large areas of dense lymphoid tissue with degenerating and disappearing acini scattered throughout. There were columnar epithelial cells showing evidence of hyperplasia. We do not know whether this hyperplasia was created by the use of thiouracil for a month or whether it was a part of the original pathologic change in the gland, but the overall picture of the microscopic slides as well as the gross specimen was that of a mild degree of Hashimoto's struma. It is interesting to note that in this 1 case of Hashimoto's struma, which is the only one we have treated with thiouracil no clinical improvement took place. This fact offers additional support to the contention that Hashimoto's struma is in no way related to acute thyroiditis.

Of the 8 patients cured, 1 deserves especial mention because of certain features. This patient's symptoms were the most severe and she had the highest temperature, 102 F. at the time of our examination, the highest white cell blood count and basal metabolism rate, and the largest gland of any of the cases here reported. She stated that the temperature had been over 103 F. She had taken Lugol's solution for three weeks without benefit when referred to us. In one week on 0.2 Gm. of thiouracil three times a day she returned with the unused portion of the drug stating that she was perfectly well and was returning the medicine in the hope that we might use it with equal benefit for some other person similarly afflicted. However, she returned in another week stating that she was not so well; that the symptoms had all recurred in milder degree. Two weeks' additional treatment with smaller doses sufficed to produce a complete cure. The gland has subsequently returned to normal size and consistency and functionally appears to be normal.

CONCLUSION

If the patient is seen and treated during the early stages of the disease, we believe that for practical purposes thiouracil may be considered a specific in acute thyroiditis.

We do not know if others have used thiouracil in the treatment of acute thyroiditis and make this report in the hope that others will use it and report their experiences.

Medical and Dental Building.

PENICILLIN TREATMENT OF ACUTE
PUERPERAL MASTITISTWENTY-FOUR CASES TREATED WITHOUT
ABSCESS FORMATIONCAPTAIN C. P. HODGKINSON
ANDCAPTAIN REUBEN E. NELSON
MEDICAL CORPS, ARMY OF THE UNITED STATES

In acute puerperal breast infections the period of cellulitis preceding abscess formation is short, and a more satisfactory treatment than incision and drainage of the resulting abscess is desirable. Although the incidence of acute puerperal mastitis is not high, the percentage going on to abscess formation is considerable. Using standard methods of treatment, McIntosh¹ showed that approximately 18.7 per cent went on to suppuration under good hospital management. Elward and Dodek,² McIntosh¹ and more recently Harvey, Spindler and Dowdy³ reported a sharp reduction in the incidence of abscess formation when small doses of roentgen therapy were used. Sulfonamide therapy has apparently failed to achieve the clinical improvement expected, probably because of the relative ineffectiveness of such drugs on staphylococcal infections. Penicillin, a more energetic drug, offers a new method of treatment.

PENICILLIN AS RELATED TO ACUTE
PUERPERAL MASTITIS

The bactericidal action of penicillin is selective. Among the organisms found to be particularly susceptible to penicillin are various streptococci, staphylococci, pneumococci, the clostridium group (especially *Clostridium welchii* and *Clostridium septicum*), gonococci, meningococci and, in addition, certain spirochetes and Actinomyces.⁴ Bacteriologic studies have shown that most acute puerperal breast infections are staphylococcal in origin. The clinical course of acute mastitis is characterized by a variable but usually short period of cellulitis followed promptly, as the case may be, by abscess or resolution. Once an abscess has formed, penicillin will not replace adequate incision and drainage. Ambitions to limit breast infections to the cellulitis stage with penicillin therapy must involve early initiation of treatment before the lytic action of the bacteria results in suppuration, when the process becomes irreversible.

RESULTS WITH PENICILLIN THERAPY

Since August 1944, 24 patients suffering from acute puerperal mastitis have presented themselves for treatment at Fitzsimons General Hospital. The average time of onset for the group was twenty-three days post partum, while the duration of illness was at least twenty-four hours. The clinical history in each case was essentially the same: sudden onset of pain in the breast, followed shortly by chills and fever. The patients were acutely ill with temperature elevations as high as

106 F., with corresponding elevations in the leukocyte and neutrophil counts. Examination on admission revealed the involved breast to be enlarged and tender, and usually a mass was found beneath an area of erythema. Occasionally the involvement was diffuse. On admission a conservative program using intramuscular penicillin was instituted in all cases. It was quickly recognized that the usual protracted clinical course was altered. Symptomatically the patients rapidly improved. All patients were afebrile within sixty hours, and the area of induration progressively lost its tenderness and diminished in size until at the time of discharge it was seldom palpable. In several instances a small mass remained which had apparently been sterilized. Recurrence of symptoms failed to develop in any case. Abscess formation was prevented in all cases and the period of hospitalization, averaging six days, was shortened.

FIVE DAY PLAN OF TREATMENT

The course of treatment used was as follows: complete bed rest until the temperature was normal, application of ice bags, and support by breast binder. The breasts were not pumped. Penicillin was administered intramuscularly in doses of 25,000 Oxford units every three hours for seventy-two hours, then 15,000 Oxford units every three hours for forty-eight hours. If the breasts were lactating, inhibition was facilitated by using diethylstilbestrol in doses of 5 mg. three times daily until a total of 40 mg. had been given. Diet and fluids were permitted as desired. All patients were discharged between the fifth and eighth days.

COMMENT

In adapting penicillin to the treatment of breast infections an understanding of the indications, contraindications and limitations of its usefulness are essential. Several factors peculiar to this type of infection appear important.

Sulfonamide Therapy.—When there was a scarcity of penicillin there was a general tendency to use it in the treatment of infections after one of the sulfonamides had failed. For excellent reasons, sulfonamide drugs are used in the puerperal state, both to prevent and combat infectious processes, an example being the use of sulfathiazole cream for cracked and fissured nipples. Although there are no specific reports available concerning the effectiveness of sulfonamide therapy in the treatment of breast infections, undoubtedly it is widely used today. Of 16 patients treated with drugs of this group during the cellulitis stage, the last 4 patients were subsequently treated with penicillin and quickly recovered. Twelve of the patients were seen before penicillin became available, and 9 required incision and drainage of an abscess. The time per patient when incision and drainage were necessary averaged 50.7 days from the onset of the infection to complete healing of the wound. From the results obtained through its use in this small series of cases, it is our impression that sulfonamide therapy is relatively ineffective in the treatment of puerperal mastitis. Early institution of penicillin therapy, without a trial of sulfonamide administration, is desirable.

Nursing State.—Acute puerperal mastitis finds its maximum incidence during the first three weeks of the postpartum period and in relation to the weaning

3. Harvey, R. A.; Spindler, H. A., and Dowdy, A. H.: Roentgen Therapy as an Adjunct in the Management of Acute Postpartum Mastitis, *Surg., Gynec. & Obst.* 80: 396-403 (April) 1945.

4. Penicillin, United States War Department, Technical Bulletin (11B MED 7), Washington, D. C. Government Printing Office, Feb. 12, 1944.

process. Careful supervision during these periods is important, as was recently stressed by Macpherson.⁵

A controversial question concerns the wisdom of continuing lactation after the breast infection has been controlled. With penicillin therapy it is possible to maintain lactation through and following the infection. That this is not desirable is illustrated by 3 of our patients who gave the history of having received penicillin for a minor breast infection during their immediate postpartum period. All apparently recovered and continued to nurse their babies after going home. When first seen by us approximately two weeks later, each had developed a severe mastitis in the contralateral breast, which responded well to the penicillin program herein described.

Dosage.—A factor of major importance in the treatment of staphylococcal infections in general is adequate dosage of penicillin. The staphylococcus notably becomes penicillin fast under inadequate dosage.⁶ The dosage used in the present series of cases has been sufficient. Clinical remission is apparently complete in most patients after sixty hours of treatment. Hence it is felt important to continue the medication until the full course has been administered to obviate the possibility of reactivation because of bacterial resistance to penicillin. The tapering off period of 15,000 Oxford units every three hours for the last two days of treatment is good insurance against this complication.

Breast Abscess.—Systemic penicillin may be of value in cases of frank abscess formation by preventing the extension of infection to adjacent lobes. Fraser⁷ reported 15 cases treated by aspiration and instillation of penicillin into the abscess cavity, with resolution without drainage in only 3 cases. He suggested using penicillin for its systemic effect at an earlier stage, feeling that local treatment offered little. Penicillin will not replace adequate incision and drainage of an abscess.

CONCLUSIONS

1. Twenty-four patients suffering from acute puerperal mastitis were treated with penicillin. All resolved without abscess formation. Eight hundred and forty thousand Oxford units was administered to each patient under a five day plan of treatment consisting of 25,000 Oxford units every three hours for seventy-two hours, then 15,000 Oxford units every three hours for forty-eight hours.

2. Sulfonamide therapy, because of its relative ineffectiveness, is not recommended as a substitute for early institution of penicillin treatment in acute staphylococcal puerperal mastitis.

PREVENTION OF INFECTIOUS HEPATITIS WITH GAMMA GLOBULIN

MAJOR W. P. HAVENS JR.
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
JOHN R. PAUL, M.D.
NEW HAVEN, CONN.

In January 1945 Stokes and Neefe¹ published the first report of the use of human gamma globulin in the prevention of infectious hepatitis. Results indicated that this prophylactic measure was effective and that the use of this substance in infectious hepatitis compared favorably with its use in measles.

In the present report it is our purpose to describe another instance of the effective use of gamma globulin as a prophylactic measure in an institutional epidemic of infectious hepatitis. The outbreak to be described occurred in a Catholic home for children in New

Haven.² This home had on Jan. 20, 1945 a population of 299 children (90 per cent of whom were between the ages of 6 and 16) and 39 adults. During the period between Nov. 5, 1944 and April 27, 1945, 53 cases of infectious hepatitis with jaundice and 56 cases of questionable hepatitis without clinical jaundice occurred at the home (chart 1). In the latter group of non-icteric cases the diagnosis was often somewhat indefinite. It was based on a sequence of symptoms similar to those usually found in the early stage of hepatitis with jaundice; namely, an acute onset with fever of 101-103 F., headache, nausea and vomiting. Generalized aches and pains were common, and pain in the abdomen was present in about half of these cases. The average duration of fever in these nonicteric cases was two days

From the Section of Preventive Medicine, Yale University School of Medicine.

This investigation was aided in part by the Commission on Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, U. S. Army.

1. Stokes, J., and Neefe, J. R.: *The Prevention and Alleviation of Infectious Hepatitis by Gamma Globulin*, J. A. M. A. 127: 144 (Jan. 20) 1945.

2. This work was made possible by the cooperation of Sister Mary Catherine Teresa and members of her staff at the St. Francis Orphan Asylum, New Haven. Dr. Joseph D'Amico of New Haven also assisted.

and they were kept in the infirmary about a week. The jaundiced patients were kept in the infirmary for two to three weeks.

There were no seriously sick patients in this outbreak. Complications were infrequent and occurred only in the icteric patients, consisting of atypical pneumonia in 1 child and generalized acute dermatitis in 2 children. One child had a relapse two and one-half weeks after discharge from his first admission to the infirmary.

Both icteric and nonicteric cases were well scattered through all the juvenile age groups represented at the institution, with no particular concentration among boys or girls. Only 1 adult contracted the disease. The institutional outbreak was coincidental with an increase in prevalence of hepatitis in the local urban population of New Haven as well as in other areas in the state of Connecticut. This was also largely a juvenile disease, for of the cases reported to the Health Department of the City of New Haven (exclusive of those at the asylum described in this paper) about 90 per cent were in children between the ages of 2 and 17 years;³ and of the cases reported during the same period from the practice of physicians in an up state community, this same juvenile prevalence accounted for about 70 per cent of the cases.⁴

The outbreak at the institution was well under way in mid-January, when the decision to test the prophylactic value of gamma globulin was first considered. For this purpose the institution's population was divided on January 27 into four groups (table 1). Primarily, 47 children (group C) who already had had hepatitis or an illness suggestive of hepatitis were eliminated from the experiment as possible immunes. Six of these children in the latter category developed a second illness on or after January 27 with jaundice in 3 and symptoms of hepatitis without jaundice in 4. Adults (group D) also were eliminated. Of the remainder, who presumably represented the susceptible population of the institution, every second and every third child was alternately selected from the alphabetical list for inoculation, giving a ratio of about 38 per cent of the susceptibles to be inoculated. They numbered 97 children and are designated as group A. The remaining 155 susceptible children (group B) were kept as uninoculated controls.

Chart 1.—The outbreak of infectious hepatitis in which gamma globulin was given as a prophylactic measure on January 27.

Gamma globulin⁵ was inoculated intramuscularly on Jan. 27, 1945 into the 97 children in group A. Doses used are listed in table 2. This amount, which ranges from 0.06 to 0.12 cc. per pound, was less by 50 to 75 per cent than that used by Stokes and Neeffe,

who employed 0.15 cc. per pound of body weight. No untoward reactions were encountered in the 97 children inoculated.

Rates at which infectious hepatitis developed in the four groups both before and after the inoculation appear in chart 2. In the inoculated children (group A) 2 cases

Chart 2.—Rates at which infectious hepatitis developed in four groups of children during an epidemic of hepatitis at an asylum. The open squares indicate cases without jaundice. The black squares indicate cases with jaundice.

of hepatitis with jaundice occurred within six days of the inoculation, and subsequently there were 6 questionable cases of hepatitis (without jaundice) in this group. A comparison of this result with that in the susceptible (group B) controls appears in the two upper panels of chart 2 and in the results listed in table 3. The reduction of cases with jaundice in the group inoculated with gamma globulin is statistically significant. The data do not furnish evidence either for or against the attenuation of the disease by the inoculation.

COMMENT

These results indicate a sharp difference in rate at which jaundice occurred in a group of children inoculated with gamma globulin during an institutional outbreak of infectious hepatitis as compared with a larger group of uninoculated controls in the same institution.

This result was achieved in an outbreak of the juvenile form of disease, which is the common form of the disease in this country.⁶

There may be a number of different types of infectious hepatitis, which represent members of one large general group, as well as a number of varieties of the related condition known as homologous serum jaundice.⁷ It is impossible to say, therefore, whether all of them would respond to the prophylactic injection of the concentrated immune bodies which are contained in gamma globulin.

Infectious hepatitis is a disease which lends itself rather well to the use of prophylactic injections in view of its long incubation period, averaging presumably about twenty-five days. This allows a period of about seventeen days after exposure in which the administration of antibodies is effective in prevention.

3. These figures are for the period of January to May 1945 and were supplied by Dr. Joseph I. Linde, health officer of New Haven.

4. Dr. James J. Derwin, Winsted, Conn., supplied these figures, which cover the period of January to April 1945.

5. The gamma globulin employed in this study was obtained through the Office of the Surgeon General, United States Army. Products of different companies were included, with lot numbers 3-1 and 3-2, 4-1 and 4-2 for the product of company S; and A9183 and B647 for company C.

Molner, J. G., and Meyer, K. F.: Jaundice in Detroit, *Am. J. Pub. Health* 30: 509 (May) 1940. Norton, J. A.: Acute Infectious Jaundice, *J. A. M. A.* 113: 916 (Sept. 2) 1939.

7. Paul, J. R.; Havens, W. P., Jr.; Sabin, A. B., and Philip, C. H.: Transmission Experiments in Serum Jaundice and Infectious Hepatitis, *J. A. M. A.* 128: 911 (July 28) 1945.

CONCLUSIONS

1. The effectiveness of intramuscular injections of gamma globulin was tested as a prophylactic measure in an institutional outbreak of infectious hepatitis.

2. In this outbreak 53 cases of hepatitis with jaundice and another 56 cases of questionable hepatitis without jaundice occurred in a population of about 300 juveniles.

3. Ninety-seven children were given gamma globulin, and the subsequent case rate of hepatitis with jaundice was compared with that in 155 children who were left as uninoculated controls. The case rate for jaundice in the controls was about ten times that noted among those who were inoculated.

4. The only 2 cases of jaundice which did occur in the inoculated children appeared within six days of the administration of gamma globulin.

5. The average dose in this experiment was approximately 0.08 cc. of gamma globulin per pound of body weight given intramuscularly. It seems to have been as effective as the larger dose of 0.15 cc. per pound used by Stokes and Neefe.

6. No evidence is brought forward in this experiment either for or against the fact that the disease might have been attenuated by the injections.

7. It appears that gamma globulin is an effective prophylactic measure against infectious hepatitis when given in the incubation period, preferably earlier than six days before the onset of symptoms. This last statement is based on the study herein reported and on the original observations of Stokes and Neefe.

ADDENDUM

Since this paper was accepted for publication, another and similar report by Gellis, Stokes and others⁸ has appeared. In it the results of a study carried out among troops in the Mediterranean theater in the fall of 1944 are listed. With a dose of gamma globulin of 10 cc. per man (about half that originally used by Stokes and Neefe) success in preventing infectious hepatitis was achieved.

Clinical Notes, Suggestions and New Instruments

COLCHICINE IN ACUTE MYELOGENOUS LEUKEMIA

W. HARDING KNEEDLER, M.D., PHILADELPHIA

The effect of colchicine in arresting mitosis of both animal and plant cells has long been known. As would be expected, rapidly growing malignant tissue is more susceptible to its effect than normal tissue. Many investigators have reported on the effect of colchicine on tumor tissue in culture and in experimental animals. On the basis of this effect on malignant cells in vitro, Dr. O. H. Perry Pepper suggested colchicine in the case of acute myelogenous leukemia herewith reported. He had tried it in 2 acute cases, in 1 of which it had no apparent effect. In the other there was a complete remission, such as sometimes occurs spontaneously, whereupon the drug was discontinued. When relapse occurred the drug was resumed, but the further course of the disease was as would have been expected without the drug.

Two references to the use of colchicine in leukemia were found in the literature. Bernard¹ gave 1 mg. of the drug by injection into the marrow twice a week in a case of acute myelogenous leukemia for a total of six doses, whereupon the

patient died. There was apparently some modification of the blood picture but not of the course of the disease. In the other case,² of chronic myelogenous leukemia, the drug was administered by mouth without benefit.

In the case reported here, when colchicine was begun the disease was acute and the symptoms were of short duration. The progress of the disease soon became less rapid, then favorable. For some months the patient showed the picture of an aleukemic leukemia (though still with a preponderance of very young forms). After losing 58 pounds (26 Kg.) there was progressive gain in weight and strength before she finally slipped into the terminal state of the disease. Colchicine was continued through the course of the disease, certainly without harmful effect and perhaps with actual though temporary benefit. The spleen was not apparently enlarged until shortly before death and then was only 1 cm. below the costal margin, nor was the white blood cell picture what would have been expected if the disease had changed from the acute to the chronic form.

REPORT OF CASE

Mrs. B. N., aged 55, about Dec. 20, 1943 began to notice irregular fever, malaise, painful swollen gums and submental and cervical adenopathy. She had had a slight tendency to spontaneous subcutaneous hemorrhage all her life (a tendency apparently inherited by her daughter). For six months before the symptoms developed, this tendency was slightly, but increasingly, more evident than before.

Blood counts had been done at various times during the preceding ten years and no abnormal findings noted. The last previous one was eight months before, and this showed white blood cells 3,500, polymorphonuclears 85 per cent, lymphocytes 15 per cent.

Examination a few days after onset showed decidedly swollen, spongy and tender gums, and cervical adenopathy, together with swelling and tenderness of the submental and parotid lymph nodes. The spleen and liver were not enlarged, and the examination was otherwise essentially negative except for several subcutaneous hemorrhages.

On December 27 the blood showed hemoglobin 11.2 Gm., 67.5 per cent, red blood cells 3,960,000, white blood cells 29,000, with 95 per cent myeloblasts and promyelocytes. A diagnosis of acute leukemia was made. (This and all subsequent counts were done by Dr. Thomas A. Cope Jr.) A count on December 30 showed white blood cells 52,700, with 83 per cent myeloblasts and promyelocytes. On Jan. 10, 1945 the hemoglobin had dropped to 8.2 Gm., 49.5 per cent; red blood cells 2,950,000. The white blood cell count had risen to 110,400, with 90 per cent myeloblasts and promyelocytes. The patient was becoming weaker and her gums were bothering her more. Dr. O. H. Perry Pepper was called in consultation at this time. He made a slide and confirmed the diagnosis of acute myelogenous leukemia, noting the almost complete lack of platelets, and suggested that colchicine be given. This drug was given in tablets of 0.5 mg. three times a day until there was some diarrhea, and then after a two day interval twice a day, until death supervened thirteen months later. Any attempt to increase the dosage seemed to be followed by diarrhea, but this dosage was well tolerated.

Following the institution of colchicine therapy on January 11 the white blood cell count rose on Jan. 20, 1944 to 145,000, with 51 per cent myeloblasts and promyelocytes and 29 per cent myelocytes. On February 14 the blood count showed hemoglobin 6.1 Gm., 37 per cent; red blood cells 1,880,000, white blood cells 4,900, myelocytes 10 per cent, stabs 22 per cent, segmented 43 per cent, lymphocytes 25 per cent. The mouth and the lymph nodes were immensely better. The fever was nearly gone, and the patient felt greatly improved, though weak. Two blood transfusions totaling 750 cc. helped to improve the anemia. On March 4 the blood showed hemoglobin 9.9 Gm., 60 per cent; red blood cells 3,660,000, white blood cells 2,400, lymphocytes 10 per cent, stabs 6 per cent, unidentified

8. Gellis, S. S.; Stokes, J., Jr.; Brother, G. M.; Hall, W. M.; Gilmore, H. R.; Beyer, E., and Morrissey, R. A.: Use of Human Immune Serum Globulin (Gamma Globulin) J. A. M. A. 128: 1062 (Aug. 11) 1945.
1. Bernard, J.: Leucémie aiguë: Essai de traitement par les injections intramédullaires de colchicine, Sang 13: 434, 1939.

2. Paul, J. T.; Brown, W. O. and Limarzi, L. R.: The Effect of Colchicine on Chronic Myeloid Leukemia, Am. J. Clin. Path. 11: 210, 1941.

cells resembling lymphocytes 84 per cent. The patient was able to be up and dressed every day at this time. Further blood transfusions of 500 cc. each were given once each in March, April and May. The mouth no longer bothered her. Her teeth, however, were still somewhat loose. In March, following cleansing by an otologist, there was bleeding from one ear which was hard to control. There was also severe dysphagia for some days, probably from a deep hemorrhage, though no lesion was found. On April 19 she was suffering much pain from an inflamed ulcerated hemorrhoid. The white blood cells at this time numbered 17,700, with 87 per cent myeloblasts and promyelocytes. On May 9 the blood showed 27,600 white blood cells, with 95 per cent myeloblasts and promyelocytes. Then a mass of glands in the right axilla developed and suppurated, being first ready for aspiration on May 20. The bleeding tendency rendered incision unsafe. The pus showed nonhemolytic *Staphylococcus aureus*. At this time the white blood cells numbered 76,900, with 98 per cent myeloblasts and promyelocytes. Blood transfusion was given two days before the abscess was aspirated and seemed to help in the suppuration. On June 19 the white blood cells numbered 31,800, with 90 per cent myeloblasts and promyelocytes. On August 9 the white blood cells numbered 10,900, with 37 per cent myeloblasts and promyelocytes. On August 14 cellulitis developed inside the right nostril, with swelling of the face. This was controlled with the help of penicillin. Later in the month an ischio-rectal abscess developed and ruptured spontaneously, with pus containing a hemolytic streptococcus and blood clots. Penicillin was not given for this.

In September the weight of the patient had dropped from 138 to 80 pounds (63 to 36 Kg.), but she felt fairly well. Her teeth, which had been loose, were now firm and her gums were normal. Fever was no longer present. The weight and strength steadily improved during the next three months, so that she regained 15 pounds (7 Kg.). There were two further episodes of infections, a paronychia which required penicillin and another pararectal abscess, which was also treated with penicillin and which ruptured spontaneously. No transfusions were given after May, but on November 17 hemoglobin was 10 Gm., 61 per cent, red blood cells numbered 3,470,000, white blood cells 7,300, myeloblasts 46 per cent, stabs 2 per cent, polymorphocytes 5 per cent, lymphocytes 15 per cent.

In the latter part of December 1944, a year after onset of acute symptoms, the patient developed nausea and anorexia, which persisted until death. It was suspected that hidden purpuric hemorrhage was a factor in this. More subcutaneous hemorrhages were noted, and she began to pass bloody urine about Jan. 18, 1945. The blood count on January 22 showed hemoglobin 6.5 Gm., 39 per cent, red blood cells 3,160,000 and white blood cells 90,200, of which 90 per cent were myeloblasts and promyelocytes. Transfusion of 500 cc. was given on January 23, but bleeding continued. This was the first transfusion since May. The blood count on January 29 showed hemoglobin 7.5 Gm., 45 per cent, red blood cells 3,170,000, white blood cells 162,000, myeloblasts and promyelocytes 81 per cent, myelocytes 9 per cent. Another blood transfusion of 500 cc. was given on February 1. Hematuria ceased two days later. Then for a week there was no bleeding, but hematuria recurred and continued until the day before death. There was also a nosebleed, which was controlled by packing once with epinephrine. The blood count on February 13 showed hemoglobin 5.5 Gm., 33 per cent, red blood cells 2,500,000, white blood cells 295,000, myeloblasts and promyelocytes 93 per cent, myelocytes 4 per cent. Further transfusions seemed useless, the rapid rise in the white count apparently being the terminal outpouring of these cells. Slides were examined by Dr. L. M. Tocantins on February 16, who reported "There were great numbers of leukocytes, a great majority of which were primitive cells (probably myeloblasts); some of these cells had Auer bodies. No platelets were seen in this smear. The red blood cells were slightly larger than normal. The blood changes are those observed in the terminal acute stage of a myeloid

leukemia." The patient became progressively weaker; cachectic edema developed, and on February 24 she lapsed into coma, dying a few hours later. No autopsy was performed.

SUMMARY

Colchicine was administered to a patient with acute myelogenous leukemia and continued until death thirteen and one-half months later. The condition did not proceed to its usual rapid termination, nor did it assume the typical characteristics of chronicity. The downhill course gradually slackened through eight months, and after a weight loss of 58 pounds (26 Kg.) there was a three month period of improvement during which 15 pounds (7 Kg.) was regained. Transfusions were unnecessary for an eight month period. The course of the disease was punctuated by the usual pyogenic infections, three of which required penicillin and three of which suppurated. A probable lifelong thrombocytopenia was apparently accentuated by the leukemia. There was nothing unusual about the terminal clinical and hematologic picture. No conclusions can be drawn regarding the beneficial effect of colchicine in this case, but further trial of the drug for the condition seems justified.

RECURRENCES OF PNEUMOCOCCIC MENINGITIS

EUGENE F. TRAUT, M.D., CHICAGO

Craddock and Bowers¹ described a patient having repeated attacks of pneumococcic meningitis. The patient of Hopkins and his co-workers² had three acute episodes of sinusitis complicated each time by pneumococcic meningitis. Recovery followed sulfonamide medication and treatment of the sinusitis.

The patient who is the subject of the present report has been under the care of Dr. E. W. Westland in the West Suburban Hospital. When first seen she was 7 years old and had always been well since an uncomplicated skull fracture two and one-half years before. Within four years she has been admitted to various hospitals for five acute attacks of pneumococcic meningitis. The organism isolated from the spinal fluid in three attacks has been type XXI. There is no known focus in the ears, respiratory tract or the accessory sinuses. X-ray examinations of the lung, skull and sinuses have been negative. In each recurrence the episode has been primary, uncomplicated by involvement of any other part of the body. In each attack the patient has responded to sulfonamides and antipneumococcus serum. The symptoms have always been violent with coma, convulsions, headache, high fever and vomiting of sudden onset.

The meningitis in each instance has recurred suddenly and violently. Within five hours after a rigor, headache and projectile vomiting she is in coma with convulsive seizures. The leukocyte count in the blood and spinal fluid rises swiftly. The spinal fluid sugar falls. Responding rapidly to type specific antipneumococcus serum and small intravenous doses of sulfonamides, she soon recovers. In her third attack she was treated in a small hospital with limited laboratory facilities. She received no serum but recovered after small doses of sulfonamide. In her fifth episode she was treated in the Michael Reese Hospital by Dr. Abraham Levinson. On this fifth admission the pneumococci in the spinal fluid were reported to be type XV. She recovered after sulfonamide had been administered for two days.

Between her first and second attacks she was apparently well for three months; between the second and third attacks, six months; between the third and fourth attacks, eleven months, and between the fourth and last attack, twelve months. The increasing intervals may indicate a rising resistance.

1. Craddock, G. B. and Bowers, R. V.: Recurrent Pneumococcic Meningitis Treated with Sulfapyridine, *J. A. M. A.* **116**: 296 (Jan. 25) 1941.

2. Hopkins, H.; Hatch, L. C.; Schenk, H. P. and Pepper, D. S.: Recurrent Pneumococcic Meningitis Treated with Sulfonamides, *Ann. Int. Med.* **20**: 333 (Feb.) 1944.

The parents of the child refuse to return her for determination of a possible further study of her spinal fluid to determine the possibility of persisting pneumococci in the spinal fluid. It has been suggested that pneumococci may be constantly present in the patient's spinal fluid without giving rise to inflammation or symptoms analogous to bacteriuria without pyuria.³

122 South Michigan Avenue, Chicago 3.

THE TREATMENT OF PERIRENAL ABSCESS WITH PENICILLIN

MAJOR E. A. OCKULY, CAPTAIN W. T. BARNHART
AND CAPTAIN H. L. EGBERT
MEDICAL CORPS, ARMY OF THE UNITED STATES

A private aged 30 had been in Africa eleven months at the time of his first hospitalization, which occurred on Sept. 4, 1943 because of malarial fever, estivoautumnal type; acute bronchitis, and chronic acne of a moderately severe nature over the shoulders and thoracic portion of his back. He was discharged to duty as cured of his malaria and bronchitis but without improvement of the acne on Sept. 13, 1943.

He was readmitted to the same hospital in Africa on three occasions after this because of recurrent malaria. These admissions were between Sept. 28, 1943 and Dec. 3, 1943.

During hospitalization following the third admission he continued to have a low grade fever of 99 to 100 F. even though his blood smears were repeatedly negative for plasmodia. He was discharged from the hospital on Jan. 31, 1944, his temperature still varying between 99 and 100 F.

Readmission was necessary on Feb. 4, 1944 because of fatigue, malaise, anorexia, nausea, vomiting and upper abdominal pain. Blood smears for malaria were repeatedly negative, the urinalyses were normal and the blood count showed a normal differential with 9,050 white blood cells and 5,670,000 red blood cells. Agglutination tests for typhoid, typhus, paratyphoid A and B and melitensis were negative. The sedimentation rate was 7 mm. in one hour. Roentgenographic gastrointestinal examination was normal except for pronounced hyperperistalsis. X-ray of the chest and routine examination of the stool were normal. Continuing the low grade fever, he remained in the hospital until April 8, 1944, at which time he was transferred to the United States.

On his way to the United States he was taken from the plane in Puerto Rico and hospitalized one day because of pain in the midportion of the upper abdomen, nausea and vomiting. His temperature was 99.2 F. at the time of his admission and he was released from the hospital twenty-four hours later.

In the United States he remained in a hospital from April 15 to June 17, 1944. Medical, dental and neurologic as well as repeated blood, stool and urine examinations were normal. During this hospitalization he had developed a large furuncle on the dorsum of the lower third of the left thigh, which spontaneously opened, drained and healed under the application of hot moist packs. His temperature during this stay in the hospital varied from normal to 99.4 F.

After a furlough he entered a redistribution station on July 4, 1944 for reprocessing and reassignment. Beginning July 15 he noticed soreness in the left costovertebral angle, which would awaken him at night and for which he would usually get out of bed, walk around and take a smoke in an attempt to be more comfortable. He stated that he was very weak, that slight exercise would produce a very coarse tremor of his hands, and night sweats were a regular occurrence.

On July 20 he had a severe chill, nausea, vomiting and an increase of the continuous aching in the left costovertebral angle. He was admitted to the A. A. F. Regional Station Hospital at Coral Gables, Fla., July 21. His temperature was 103 F., there was severe pain in the left upper abdomen and back, and an admitting diagnosis of recurrent malaria was made. Repeated blood smears were negative for malarial parasites. Because of the persistent pain in the left costovertebral angle and fever

of from 99 to 103 F., he was seen in consultation by the urologic department on July 28. He had been treated with sulfadiazine from July 24 to July 28 with no improvement in the pain or his fever. There were no urinary symptoms.

At the time of examination the temperature was 102.8 F., he appeared moderately anxious, his tongue was coated and the examination showed that there was muscle guard and tenderness to palpation over the left kidney. A questionable mass could be felt in the left upper abdomen, but because of the muscle guard this could not be definitely established. However, there was visible bulging in the area of the left costovertebral angle and this was decidedly tender. A diagnosis of left perirenal abscess was made. The intravenous urograms revealed an obliteration of the left psoas shadow and a mesial displacement of the upper third of the left ureter with otherwise normal pyelograms and evident good bilateral renal function. The urine was normal except for an occasional pus cell, the white blood cell count was 14,000 and the blood sulfadiazine level was 8.2 mg. per hundred cubic centimeters.

Continuous intravenous penicillin therapy was administered at the rate of 60,000 to 125,000 units every twenty-four hours. His temperature gradually dropped to normal over a period of eight days. The penicillin therapy was continued for two days after the temperature was normal, until a total of 925,000 penicillin units had been administered.

Within forty-eight hours after starting the penicillin therapy the patient felt very much better, muscle guard over the upper abdomen disappeared and there was definite diminution in size of the tender mass in the left costovertebral angle. After

ninety-six hours there was no visible evidence of any mass remaining, and although the temperature ranged between 99 and 101 F. the patient felt perfectly well, in fact, better than he had felt for many months. By the eighth day his temperature was normal and he was free of any signs or symptoms that were present at the time of his admission to the hospital. The patient was discharged to duty as cured on Aug. 27, 1944 after his temperature had been normal and he had been free of any complaints for three weeks. We are in receipt of a communication dated Jan. 15, 1945 (somewhat more than five months after completion of the penicillin therapy) showing that no symptoms referable to a possible recurrence have appeared.

Although we have no proof that free pus was present, all the classic clinical symptoms and findings of perirenal abscess were present. Except for the desire to exploit the value of penicillin, there was no doubt in our minds that incision and drainage were indicated at the time penicillin therapy was begun.

As far as we know, this is the first case treated and cured with penicillin therapy. It naturally provides the interesting speculation that perhaps another heretofore surgical condition has become, in at least certain selected instances, amenable to chemotherapy.

The Average Length of Life.—The average length of life in India is only twenty-seven years, whereas that for Japan is forty-six years, for Great Britain sixty-two years and, for the United States, approximately sixty-two years. Yet, in spite of such high mortality rates and the short length of life, India's population has increased by more than 250,000,000 in the past ninety years.—Simmons, James S., and others: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

THE ORGANIZATION AND RESULTS OF HEALTH MAINTENANCE-CANCER PREVENTION CLINICS

MILDRED W. S. SCHRAM, Ph.D.
Secretary, International Cancer Research Foundation
PHILADELPHIA

In view of the findings in three cancer prevention clinics which have been in operation for from four to seven years, the International Cancer Research Foundation has established in the city of Philadelphia a series of clinics for the conservation of health. This has been done for a five year period on an experimental basis. It might be dubbed a five year plan or even a "noble experiment." In any case Philadelphia will be the laboratory in which data will be gathered on which may be based valid conclusions as to the future of such examining centers. That they are essential to the good health of the nation may be considered as hardly open to question in view of the findings at Selective Service examinations and at recent examinations of school children in Philadelphia. Figures of the latter are sufficiently arresting to warrant quoting here. Of 170,260 pupils examined 68,823 were found normal. Only 40 per cent! Doesn't that give one pause?

Be that as it may, the objective of the present experiment is to provide adequate data for statistical evaluation. Present indications are that there will be about twenty-five hundred examinations a year. From a research point of view, much of the ultimate value of these clinics will be the data accumulated over the years. To this end, especial care has been given to preparation of the forms. All clinics are requested to use these forms to insure uniformity of data.

The clinics do not give treatments. Their one function is examination, with special emphasis on conditions which may lead to cancer. Complete physical examinations are given, including the skin, mouth, tongue, pharynx, larynx, breast, pelvis, rectum and lymph nodes, routine laboratory tests—blood count, urinalysis and Wassermann-Kline tests—and a routine chest film. When special studies are indicated, e. g. cystoscopy, biopsy, or gastrointestinal series, these will be done wherever the examinee or his physician desire.

Whenever there is a positive finding, the examinee is referred back to his physician. If he has no physician he is given a list of names of physicians in his vicinity. If he cannot afford a physician he is given the names of several hospitals, from which he will make his choice. When medical attention of any kind is indicated, a letter is sent to the personal physician noting the findings and advising as to consultation or whatever is relevant. Should the condition be urgent there is a follow-up telephone call within a week or two. If the condition is not serious the follow-up may be deferred for some weeks. A record is kept of what treatment is administered, where, when and by whom. Records will be available to all personal physicians and also, eventually, for studies by those qualified to undertake them.

If the examinee cannot afford to make the usual contribution toward the expenses of the examination, this is adjusted to his ability to pay. Should special studies be required for which he is unable to pay, the foundation will reimburse the institution concerned for the cost of such studies.
